# Introduction

BLUPF90 is a family of programs for mixed-model computations with focus on animal breeding applications. The programs can do data conditioning, estimate variances using several methods, calculate BLUP for very large data sets, calculate approximate accuracy, and use SNP information for improved accuracy of breeding values + for genome-wide association studies (GWAS). The programs have been designed with 3 goals in mind:

- 1. Flexibility to support a large set of models found in animal breeding applications.
- 2. Simplicity of software to minimize errors and facilitate modifications.
- 3. Efficiency at the algorithmic level.

Aside from being used in hundreds of studies, the programs are utilized for commercial genetic evaluation in dairy, beef, pigs and broiler chicken by major companies/institutions/associations in the US and beyond.

The programs are written in Fortran 90/95 and originated as exercises for a class taught by Ignacy Misztal at the University of Georgia. Over time, they have been upgraded and enhanced by many contributors. Details on programming and computing algorithms are available in an Interbull 1999 paper and as course notes. Nearly all programs are available in source code.

Online information about the programs is available at <a href="http://nce.ads.uga.edu/wiki/doku.php">http://nce.ads.uga.edu/wiki/doku.php</a> as wiki pages. There is discussion group blupf90 at groups.yahoo.com.

# List of programs from Wiki page

Latest versions available from website at

http://nce.ads.uga.edu/wiki/doku.php?id=application\_programs

(Use latest versions. All applications for Linux, Mac OSX, and Windows have been updated frequently)

The programs support mixed models with multiple-correlated effects, multiple animal models and dominance.

- BLUPF90 BLUP in memory
- REMLF90 accelerated EM REML
- QXPAK joint analysis of QTL and polygenic effects (M. Perez-Enciso) QxPak web page
- AIREMLF90 Average Information REML with several options including EM-REML and heterogeneous residual variances (S. Tsuruta)
- CBLUP90 solutions for bivariate linear-threshold models
- CBLUP90THR as above but with thresholds computed and many linear traits (B. Auvray)
- CBLUP90REML as above but with quasi REML (B. Auvray)
- GIBBSF90 simple block implementation of Gibbs sampling
- GIBBS1F90 as above but faster for creating mixed model equations only once
- GIBBS2F90 as above but with joint sampling of correlated effects
- GIBBS3F90 as above with support for heterogeneous residual variances
- POSTGIBBSF90 statistics and graphics for post-Gibbs analysis (S. Tsuruta)
- THRGIBBSF90 Gibbs sampling for any combination of categorical and linear traits (D. Lee)
- THRGIBBS1F90 as above but simplified with several options (S. Tsuruta)
- **RENUMF90** a renumbering program that also can check pedigrees and assign unknown parent groups; supports large data sets
- INBUPGF90 a program to calculate inbreeding coefficients with incomplete pedigree (I. Aguilar)
- SEEKPARENTF90 a program to verify paternity and parent discovery using SNP markers (I. Aguilar)
- **PREDICTF90** a program to calculate adjusted y,  $\hat{y}$ , and residuals (I. Aguilar)
- PREDF90 a program to predict direct genomic value (DGV) for animals based on genotypes and SNP solution

#### Available by request

- MRF90 Method R program suitable for very large data sets; contact T. Druet.
- COXF90 Bayesian Cox model contact J. P. Sanchez (JuanPablo.Sanchez@irta.cat)
- BLUPF90HYP BLUPF90 with hypothesis testing (F and Chi2 tests) contact J. P. Sanchez as above

#### Available only under research agreement

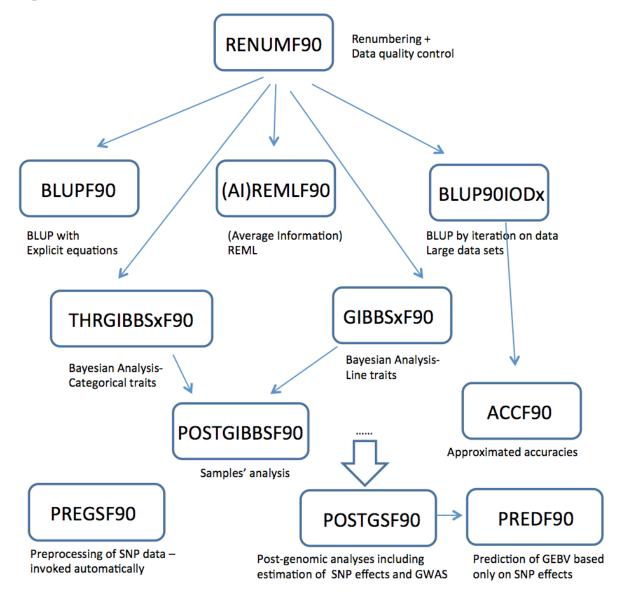

- BLUP90IOD2 BLUP by iteration on data with support for very large models (S. Tsuruta)
- CBLUP90IOD BLUP by iteration on data for threshold-linear models
- ACCF90 approximation of accuracies for breeding values
- BLUP90MBE BLUP by iteration on data with support for very large models for multi-breed evaluations
- BLUP90ADJ BLUP data preadjustment tool

### Included in application programs

- PREGSF90 genomic preprocessor that combines genomic and pedigree relationships (I. Aguilar)
- POSTGSF90 genomic postprocessor that extracts SNP solutions after genomic evaluations (single step, GBLUP)
   (I. Aguilar)

Other programming contributions were made by Miguel Perez-Enciso (user\_file) and François Guillaume (Jenkins hashing functions).

# Programs in a chart

Application programs (BLUP\*, \*REMLF90, THRGIBBS\*, and GIBBS\*) are driven by parameter files and require data files with effects renumbered from 1 consecutively.

Renumbering and quality control can be done by RENUMF90, which is also driven by a parameter file. Separation of renumbering and application programs allows supporting complicated models.

Some models are not directly supported by RENUMF90 and require tweaking the parameter file in the application programs.

# Parameter file for application programs

The parameter file has keywords that are fixed and cannot be changed followed by values, with the following structure (the following example comes from 2-trait maternal model):

Keywords*	Description
DATAFILE	Name of file with phenotypes; free fortran format (space-delimited file)
file.dat	
NUMBER OF TRAITS	Number of traits
2	
NUMBER OF EFFECTS	Number of effects in a model except for residual
6	
OBSERVATIONS(S)	Position(s) of observations in data file
1 2	
WEIGHTS	Position of weight on observations if used; otherwise blank
2	"2" means that residual variance (R) is set to R/2.
EFFECTS: POSITIONS_IN_DATAFILE NUM	BER_OF_LEVELS TYPE_OF_EFFECT [EFFECT NESTED]
4 4 10 cross	4 4 = crossclassified effect positions in data file for 2 traits; 10 = levels
5 0 100 cross	<b>5 0</b> = crossclassified effect, positions for 2 traits; <b>100</b> = levels
6 6 1 cov	6 6 = covariable positions in data file
7 7 10 cov 4 4	7 7 = covariable nested in effect position 4; 10 = levels
8 8 1000 cross	<b>8 8</b> = crossclassified effect positions for 2 traits; <b>1000</b> = levels
0 9 1000 cross	<b>0 9</b> = crossclassified effect positions for 2 traits; <b>1000</b> = levels
RANDOM_RESIDUAL_VALUES	Residual variance or residual covariance matrix
10 1	For 2 trait model
1 10	
RANDOM_GROUP	List of effect numbers that form a group
5 6	For correlated random effects 5 6
RANDOM_TYPE	Type of random effect (distribution)
add_animal	diagonal, add_sire, add_an_upg, add_an_upginb, par_domin, or user_file
FILE	Pedigree file or other file associated with random effect; blank if none
file.ped	
(CO)VARIANCES	(Co)variance matrix for each random effect
10 1 0 1	For 2 trait model
1 10 0 1	
0 0 0 0	
1 1 0 10	

<sup>\*</sup>Keywords need to be typed exactly (up to 20 characters). When preparing a new parameter file, consider modifying an existing file.

Note that this parameter file is for application programs (BLUPF90, AIREMLF90, GIBBSF90 etc.) and it is not for RENUMF90. This program needs a different type of parameter file. See page 15 for details.

# **Description of effects**

The effects are specified after the keyword:

# EFFECTS: POSITIONS\_IN\_DATAFILE NUMBER\_OF\_LEVELS TYPE\_OF\_EFFECT [EFFECT NESTED]

Each line contains the following:

- Position(s) of each effect in the data file; t positions for t traits
- Number of levels (assumed consecutive from 1)
- Type of effect: "cross" for crossclassified, and "cov" for covariable
  - o crossclassified uses integer number from 1
  - o covariable uses integer or real numbers
- For nested covariables, the following number (or t numbers for t traits) indicates the position of nesting in the data file
- Text after # can be used as a comment

Consider a data file (file.dat) with the following columns

i	j	k	y1	<b>y</b> 2	<b>x</b> 1
2	2	3	4.30	5.67	22.40
1	2	2	2.76	3.20	18.00
3	1	1	2.20	5.30	7.25

Let i go from 1 to 50, j from 1 to 80, and k from 1 to 200. The model:

$$y1_{ij}=a_j+b_i+cX+e_{ij}$$

will be specified in the parameter file as:

```
DATAFILE
```

file.dat

NUMBER\_OF\_TRAITS

1

NUMBER\_OF\_EFFECTS

3

**OBSERVATIONS(S)** 

4

**WEIGHTS** 

EFFECTS: POSITIONS\_IN\_DATAFILE NUMBER\_OF\_LEVELS TYPE\_OF\_EFFECT [EFFECT NESTED]

2 80 cross # position 2, 80 levels

150 cross # position 1, 50 levels

6 1 cov # covariable on position 6, one level

.....

By definition, a regular covariable has one level (i.e., a slope as regression).

For a similar model but with a nested covariable:

```
y1_{ij}=a_i+b_i+c_iX+e_{ij}
```

The description will change to:

```
EFFECTS: POSITIONS_IN_DATAFILE NUMBER_OF_LEVELS TYPE_OF_EFFECT [EFFECT NESTED]
```

2 80 cross # position 2, 80 levels

1 50 cross # position 1, 50 levels

6 50 cov 1 # covariable on position 6 nested in position 1; 50 levels

Assume a two trait model:

$$y1_{ij}=a1_{j}+ c1_{i}X+e1_{ij}$$
  
 $y2_{ij}= b2_{i}+c2_{i}X+e2_{ij}$ 

This corresponds to:

....

NUMBER\_OF\_TRAITS

2

NUMBER\_OF\_EFFECTS

3

EFFECTS: POSITIONS\_IN\_DATAFILE NUMBER\_OF\_LEVELS TYPE\_OF\_EFFECT [EFFECT NESTED]

2 0 80 cross # position 2 for trait 1 only, 80 levels

0 1 50 cross # position 1 for trait 2 only, 50 levels

6 6 50 cov 1 1 # covariable on position 6 for two traits nested in position 1

"0" in effect definitions means missing effect per trait.

Two effects above can be merged:

# NUMBER\_OF\_EFFECTS

2

EFFECTS: POSITIONS\_IN\_DATAFILE NUMBER\_OF\_LEVELS TYPE\_OF\_EFFECT [EFFECT NESTED]

- 2 1 80 cross # positions 2 and 1 for traits 1 and 2, 80 is max(50,80)levels
- 6 6 50 cov 1 1  $\,$  # covariable on position 6 for two traits nested in position 1

### **Definition of random effects**

**RANDOM\_GROUP** defines one group of random effects. A group is one effect or multiple (correlated) effects that share the same covariance structure, e.g., direct-maternal effect or random regressions.

The structure of **RANDOM GROUP** is:

```
RANDOM_GROUP
Corresponding to the effect number specified above; "5" means that the 5<sup>th</sup> effect is random. Or "5 6" means that 5<sup>th</sup> and 6<sup>th</sup> are correlated random effects.

or
5 6
```

**RANDOM\_TYPE** defines a covariance structure: diagonal var() =  $s \otimes I$  or **G** where s is a variance and **G** is a covariance matrix. For other types, see "Random effects and Pedigree files"

Assume a model:

```
y = farm + animal_additive + animal_environment + error with var(animal_additive) = 2.5\otimes \mathbf{A}, var(animal_environment) = 5.1\otimes \mathbf{I}, var(error) = 13.7\otimes \mathbf{I}
```

With these effects:

```
EFFECTS: POSITIONS_IN_DATAFILE NUMBER_OF_LEVELS TYPE_OF_EFFECT [EFFECT NESTED]
3 100 cross # effect 1: farm
2 1000 cross # effect 2: additive genetic
2 1000 cross # effect 3: permanent environment
RANDOM_RESIDUAL_VALUES
13.7
RANDOM_GROUP
                 # this is for effect 2 on the effect list
RANDOM_TYPE
add_animal
                 # additive genetic
FILE
file.ped # name of pedigree file
(CO)VARIANCES
2.5
RANDOM_GROUP
                 # effect 3 on the effect list above
RANDOM_TYPE
diagonal # permanent environment
FILE
                 # no file associated with diagonal structures
(CO)VARIANCES
5.1
```

#### **Correlated effects**

Assume a model:

```
y = farm + season + direct + maternal + error var(direct,maternal)= \begin{bmatrix} 5 & 1 \\ 1 & 6 \end{bmatrix} \otimes A
```

with the effects as specified:

# EFFECTS: POSITIONS\_IN\_DATAFILE NUMBER\_OF\_LEVELS TYPE\_OF\_EFFECT [EFFECT NESTED]

3 100 cross # effect 1: farm
 4 4 cross # effect 2: season
 2 1000 cross # effect 3: direct
 2 1000 cross # effect 3: maternal

The distribution of the random effects are specified below:

...

RANDOM\_GROUP

3 4 # direct and maternal effects

RANDOM\_TYPE

add\_animal # additive genetic

FILE

file.ped # name of pedigree file

(CO)VARIANCES

Random regression models may have many correlated random effects. Assume a data file with the following positions:

1 to 4: polynomials

animal number (1000 levels)herd year season (50 levels)

...

EFFECTS: POSITIONS\_IN\_DATAFILE NUMBER\_OF\_LEVELS TYPE\_OF\_EFFECT [EFFECT NESTED]

6 50 cross # herd year season

1 1000 cov 5 # first polynomial nested within the animal effect position 5
 2 1000 cov 5 # second polynomial nested within the animal effect position 5
 3 1000 cov 5 # third polynomial nested within the animal effect position 5
 4 1000 cov 5 # fourth polynomial nested within the animal effect position 5

••••

RANDOM GROUP

2 3 4 5 # all covariables are correlated (effects 2, 3, 4, and 5 on the list above)

RANDOM\_TYPE

add\_animal # additive genetic

FILE

file.ped # name of pedigree file

(CO)VARIANCES (4 x 4 matrix) There are a few types of additive genetic effects, each with a different pedigree format.

a) additive sire (add\_sire)

The pedigree file has the following format:

sire number, sire's sire number, sire's maternal grandsire (MGS) number

where unknown sire's sire and/or sire's MGS numbers are replaced by 0.

b) additive animal (add animal)

The pedigree file has the following format:

animal number, sire number, dam number

where unknown sire and/or dam numbers are replaced by 0.

c) additive animal with unknown parent groups (add\_an\_upg)

The pedigree file has the following format:

animal number, sire number, dam number, parent code

where sire and/or dam numbers can be replaced by unknown parent group numbers

parent code = 3 - number of known parents:

- 1 (both parents known)
- 2 (one parent known)
- 3 (both parents unknown)
- d) additive animal with unknown parent groups and inbreeding (add\_an\_upginb)

The pedigree file has the following format:

animal number, sire number, dam number, inb/upg code

where sire and/or dam numbers can be replaced by unknown parent group numbers

inb/upg code = 4000 / [(1+ms)(1-Fs) + (1+md)(1-Fd)]

where ms (md) is 0 whenever sire (dam) is known, and 1 otherwise, and Fs(Fd) is the coefficient of inbreeding of the sire (dam). For example, the inb/upg code for the animal with both parents known is 2000. The code should be an integer value.

e) parental dominance (par domin)

The pedigree class file has the following format:

s-d s-sd s-dd ss-d ds-d ss-sd ss-dd ds-sd ds-dd code

where x-y is a combination number of animals x and y, s is sire, d is dam, sd is sire of dam, etc.

Code is a number of 0 to 255 and refers to the combination of missing subclasses. If one line is:

then code =  $\sum_{i=0}^{7} (a_i \times 2^i)$  where  $a_i = 0$  if  $s_i > 0$ , or  $a_i = 1$  otherwise.

For example, the code for a line with all nonzero parental subclasses is 255. For a line with only zero parental subclasses, If classes are ordered so that lines with zero parental subclasses, code=0. If lines are ordered so that p for parental classes with code=0 are ordered last, they may be omitted and will added automatically. The parental dominance file can be created by program **RENDOMN**.

f) user provided matrix (user\_file)

A file specified in FILE contains the inverse of a matrix in the following format:

row col value

as lower- or upper-triangular elements (but not full stored). The matrix is used directly by application programs. For example, to use a genomic relationship matrix G, the file needs to contain  $G^{-1}$ .

g) user provided matrix with inversion (user\_file\_inv)

As above but the matrix in FILE is inverted by the application programs before being used. For example, to use a genomic relationship matrix G, the file needs to contain G. The inversion is by sparse matrix techniques so it is efficient for sparse matrices but slow for dense matrices.

# **Data and Pedigree files**

All files are free format, with fields separated by spaces. By default, 0 is a missing value for all effects, including covariables.

# <u>Transferring a file from Windows (DOS) to Linux environment</u>

Use "dos2unix" to convert the DOS (Windows) format to the UNIX (Linux) format if the programs show an error message while reading a file ("flip –u" can be also used instead of "dos2unix").

#### Data file

- a. Space(s) is a delimiter. At least one character space between columns is required.
- b. Dot (.) is just one character but not a missing value (default missing value = 0).
- c. Check the data again especially when converting from another format or software such as EXCEL, SAS, ...
- d. For Gibbs sampling programs with "OPTION cont", copy the previous output files somewhere else just in case making mistakes and replacing those files.

# Pedigree file

- a. An original pedigree file for RENUMF90 can include alpha-numeric characters with free format.
- b. Remove duplicates.
- c. Use 0 for unknown parent(s).

# Error messages in parameter file

- a. Wrong data file name
  - Check outputs for the data file name and the number of records on the screen. The program will not stop if the wrong file name already exists.
- b. Wrong pedigree file name
  - Check output for the pedigree file name and the number of animals on the screen. The program will not stop if the wrong file name exists.
- c. Wrong positions or formats for observations and effects
  - Program may not stop and may get wrong results. Check outputs for the number of levels for each effect on the screen.
- d. Missing or skipping one or more fixed lines in the parameter file Program may stop. Check the missing line.
- e. Misspelling
  - Program may stop. Correct the wrong spelling.
- f. Missing an empty last line
  - Program may not stop. Parameter, data, and pedigree files may need one more extra line at the end of the file.
- g. (Co)variance matrix is not symmetric, not positive definite, not right sized, ...
  - Program may not stop.
- h. A good result does not mean that your parameter file is correct. Always double-check!

# RENUMF90 parameter file

# Basic rules for RENUMF90 parameter file

RENUMF90 is a renumbering program to create input (data, pedigree, and parameter) files for BLUPF90 programs and provide basic statistics. Note that RENUMF90 uses a different type of parameter file as used in BLUPF90 or other programs. RENUMF90-specific parameter file should be prepared as follows.

- The file consists of pairs of keyword and the corresponding value(s). The keyword is always capital.
- First 7 keywords are mandatory and must appear in the following order: DATAFILE, TRAITS,
   FIELDS\_PASSED TO OUTPUT, WEIGHT(S), RESIDUAL\_VARIANCE and EFFECT. If you don't actually need FIELDS\_PASSED TO OUTPUT and WEIGHT(S), simply put the empty line as a value.
- The remaining keywords are optional but appear in the specific order shown below. For
  example, the FILE keyword must be followed by FILE\_POS (or by SNP\_FILE if FILE\_POS is
  omitted; or by PED\_DEPTH if both FILE\_POS and SNP\_FILE are omitted, and so on).
- Several **OPTION** lines can be included. RENUMF90 interpret a few options. Other options are simply passed through the template parameter file for BLUPF90 (*renf90.par*).

### Parameter file

**RANDOM** 

**OPTIONAL** 

```
DATAFILE
           # data file name – input files cannot contain character # because it is used as a comment.
f_1
TRAITS
                 # positions of traits in data file
t_1 t_2 t_3 ...
FIELDS_PASSED TO OUTPUT
p<sub>1</sub> p<sub>2</sub> .. p<sub>m</sub>
                 # positions that are not renumbered; put empty line if not needed.
WEIGHT(S)
                 # position of weight - fraction to the residual variance; put empty line if not needed.
W
RESIDUAL_VARIANCE
                 # matrix of residual (co)variances
EFFECT
e_1 e_2 e_3 \dots type form
                          \# e_1 e_2 e_3 \dots = position of this effect for each trait
                          # type = 'cross' for crossclassified or 'cov' for covariables
                          # form = 'alpha' for alphanumeric or 'numer' for numeric (form is only for cross)
EFFECT
d_1 d_2 d_3 \dots cov + d_1 d_2 d_3 \dots = positions of covariables nested in the following cross-classified effects
```

e<sub>1</sub> e<sub>2</sub> e<sub>3</sub> ... form # e<sub>1</sub> e<sub>2</sub> e<sub>3</sub> ... = positions of cross-classified effects nested

random\_type # 'diagonal', 'sire' or 'animal' for random effect

# form = 'alpha' for alphanumeric or 'numer' for numeric

0<sub>1</sub> 0<sub>2</sub> 0<sub>3</sub> ... # 'pe' for permanent environment, 'mat' for maternal, and 'mpe' for maternal

permanent environment

FILE

fped # pedigree file name

**FILE POS** 

animal sire dam alt\_dam yob # positions of animal, sire, dam, alternate dam (recipient dam), and year

of birth in pedigree file (default 1 2 3 0 0).

SNP\_FILE

fsnp

# specify a SNP file with ID and SNP information; the relationship matrix will include the genomic information; a fsnp file should start with ID with the same format as fped, and SNP info needs to start from a fixed column and include digits 0, 1, 2 and 5 (5 is for missing SNP);

ID and SNP info need to be separated by at least one space; see more information in http://nce.ads.uga.edu/wiki/doku.php?id=readme.pregsf90.

PED\_DEPTH

p # depth of pedigree search (default 3); all pedigrees are loaded if p = 0.

**GEN\_INT** 

min avg max

# minimum, average, and maximum generation interval; applicable only if year of birth present in pedigree file; minimum and maximum used for pedigree checks; average used to predict year of birth of parent with missing pedigree.

**REC\_SEX** 

sex

# if only one sex has records, specifies which parent it is; used for pedigree checks.

UPG\_TYPE

t

# 'yob' = based on year of birth; if 'in\_pedigrees', the value of a missing parent should be -x, where x is UPG number that this missing parent should be allocated to; in this option, all known parents should have pedigree lines, i.e., each parent field should contain either the ID of a real parent, or a negative UPG number. If it is 'internal', allocation is by a user-written function custom\_upg (year\_of\_birth,sex,ID, parent\_code).

#### **INBREEDING**

S

# use of inbreeding coefficients to compute inb/upg code in the 4<sup>th</sup> column of the output pedigree file; if 'pedigree', the program computes inbreeding coefficients with Meuwissen and Luo (1992) using the pedigree to be saved in renaddxx.ped; calculated inbreeding coefficients will be saved in a file "renf90.inb" with the original ID; if 'file', the program reads inbreeding coefficients from an external file. You should put the filename after 'file' e.g. 'file inbreeding.txt'. The file has at least 2 columns: original\_ID and inbreeding value (from 0.0 to 1.0). The program just skips unnecessary IDs.

#### (CO)VARIANCES

G # (co)variances for animal effects or animal + maternal effects

#### (CO)VARIANCES PE

GPE # (co)variances for the PE effect

(CO)VARIANCES\_MPE

#### GMPE # (co)variances for the MPE effect

# **Combining fields**

How can we specify interactions? - Combining fields or interactions. Several fields in the data file can be combined into one using a **COMBINE** keyword.

**COMBINE** a b c .... # keywords COMBINE need to be on top of the parameter file, but possibly after comments.

#### For example:

# **COMBINE 7 2 3 4**

combines content of fields 2 3 4 into field 7; the data file is not changed, only the program treats field 7 as fields 2 3 4 put together (without spaces). The combined fields can be treated as "numeric" with the total length is < 9 or "alpha". The keyword is optional but must be placed in the top of the parameter file.

#### **Options**

RENUMF90 parameter file can accept few options. If the program detects non-RENUMF90 options, such option lines are simply passed through *renf90.par*.

#### **OPTION alpha\_size** nn # new size

Change the maximum size of character fields (default 20 characters).

# **OPTION** max\_string\_readline nn

Change the maximum length of characters in a line (default 800 characters).

# **OPTION** max\_field\_readline nn

Change the maximum number of fields capable in a line (default 100 fields).

# **Output files**

RENUMF90 generates several files.

- renf90.par: parameter template file for BLUPF90
- renf90.tables: table relating the original code and the renumbered code
- renf90.dat: data file for BLUPF90
- renaddxx.ped: pedigree file for BLUPF90; xx is an integer number that indicates the position of animal effect among all model effects in renf90.par. This file will be created only if RANDOM animal is specified.
- SNPfile\_XrefID: cross-reference file for genomic analysis, which contains renumbered ID and
  original ID; SNPfile is the original SNP marker file. This file will be created only if SNP\_FILE is
  specified.
- renf90.inb: inbreeding coefficients. This file will be created only if **INBREEDING pedigree** is specified.

# Output pedigree file

The additive pedigree file built by RENUMF90 is renaddxx.ped. The pedigree file has the following structure:

- 1) animal number (from 1)
- 2) parent 1 number or unknown parent group number for parent 1
- 3) parent 2 number or unknown parent group number for parent 2
- 4) 3 minus number of known parents (this column is replaced by inbreeding code if **INBREEDING pedigree** is specified)
- 5) known or estimated year of birth (0 if not provided)
- 6) number of known parents (if genotypes are used: 10 + number of known parents)
- 7) number of records
- 8) number of progenies as parent 1
- 9) number of progenies as parent 2
- 10) original animal id

# **BLUP**

**BLUPF90** sets up equations in memory. It can support a few million equations with a simple model to much smaller with complicated models (multiple traits, maternal effects, random regression, etc). BLUPF90 uses three solvers, chosen with options. PCG is the default solver and is usually the fastest one. SOR require less memory but usually converges slower. Sparse Cholesky (FSPAK) is usually the most accurate method but uses the most memory. The following options are available:

#### **OPTION conv\_crit 1e-12**

Set convergence criteria (default 1e-10).

#### **OPTION maxrounds 10000**

Set maximum number of rounds (default 1000).

# **OPTION solv\_method FSPAK**

Selection of solving method: FSPAK, SOR or PCG (default PCG).

#### **OPTION** r\_factor **1.6**

Set relaxation factor for SOR (default 1.4).

#### **OPTION sol se**

Store solutions and s.e. If this option is used, the solving method will turn to FSPAK.

#### **OPTION blksize 3**

Set block size for preconditioner (default 1).

# **OPTION** use\_yams

Run the program with YAMS (modified FSPAK). The computing time can be dramatically improved compared to when solv\_method is FSPAK.

### **OPTION hetres int 5 10**

The position (5) to identify the interval in the data file and the number of intervals (10) for heterogeneous residual variances as used in GIBBS3F90.

#### **OPTION fixed var file**

**BLUP90IOD2** uses an iteration on data algorithm. It can handle hundreds of millions of equations with complicated models in a reasonable time. However, it is only available based on a research with UGA. The following options are available:

# OPTION conv\_crit 1e-12

Set convergence criteria (deault 1e-12).

#### **OPTION maxrounds 10000**

Set maximum number of rounds (default 5000).

#### **OPTION blksize 3**

Set block size for preconditioner (default 1). Usually **blksize** number will be the same as the number of traits.

# OPTION init\_eq 10

Set the number of effects to be solved directly (default 0).

# **OPTION solv\_method FSPAK**

Solving method for initial equations (default DIRECT).

#### **OPTION tol 1d-12**

Tolerance to get a positive definite matrix (default 1d-12).

#### **OPTION** residual

y-hat and residuals will be included in "yhat\_residual".

#### **OPTION avgeps 50**

Using the last 50 average eps for convergence.

#### **OPTION** cont 1

To restart the program from the previous solutions.

# **OPTION missing -1**

Set the missing value (default 0).

#### **OPTION restart 100**

Set the number of iteration to recompute residuals (default 100).

# **OPTION prior\_solutions**

Using the previous solution file to start the iteration. Additional software is required to use this option.

#### OPTION random\_upg 1 2

Set the UPG random. "1" is the computational algorithm used; only algorithm 1 is implemented. "2" is the weight ( $\gamma$ ) for the group effects, the weight will be inverted (e.g., 1/2=0.5).

# OPTION SNP\_file snp

Specify the SNP file name snp to use genotype data.

# Variance component estimation

There is not a single-best choice for variance component estimation. Programs below offer choices for simple and complicated models. For advice on what works best under your circumstances, google a paper "Reliable computing in estimation of variance components".

**REMLF90** uses EM REML. For most problems it is the most reliable algorithm but can take hundreds of rounds of iteration. REMLF90 was found to have problems converging with random regression models. In this case, using starting variances that are too large than too small usually helps. Also, EM does not calculate standard errors for the estimates. The following options are available:

#### **OPTION** conv crit 1d-12

Convergence criterion (default 1d-12).

#### **OPTION maxrounds 10000**

Maximum rounds (default 5000).

#### **OPTION sol se**

Store solutions and se.

#### **OPTION residual**

y-hat and residuals will be included in "yhat\_residual".

# **OPTION missing -999**

Specify missing observations (default 0).

#### **OPTION** constant\_var 5 1 2

5: effect number, 1: first trait number, 2: second trait number implying the covariance between traits 1 and 2 for effect 5 is fixed.

#### **OPTION SNP\_file snp**

Specify the SNP file name **snp** to use genotype data.

#### **OPTION** use yams

Run the program with YAMS (modified FSPAK). The computing time can be dramatically improved.

**AIREMLF90** uses Average Information REML. It usually converges much faster but sometimes does not converge. Very slow convergence usually indicates that the model is over parameterized and there is insufficient information to estimate some variances. AI REML calculates standard errors for the estimates. The following options are available:

# OPTION conv\_crit 1d-12

Convergence criterion (default 1d-12).

#### **OPTION maxrounds 500**

Maximum rounds (default 5000). When it is zero, the program calculates BLUP without running REML.

#### **OPTION EM-REML 10**

Run EM-REML for the first 10 rounds to get initial variances within the parameter space (default 0).

#### **OPTION tol 1d-18**

Tolerance (or precision) for positive definite matrix and G-inverse subroutines (default 1d-14).

#### **OPTION sol se**

Store solutions and s.e.

#### **OPTION missing -1**

Set the missing observation (default 0).

#### **OPTION** constant\_var **5 1 2**

5: effect number, 1: first trait number, 2: second trait number implying the covariance between traits 1 and 2 for effect 5 is fixed.

# **OPTION use\_yams**

Run the program with YAMS (modified FSPAK). The computing time can be dramatically improved.

# **OPTION fact\_once memory**

Save Cholesky factor of LHS in memory. It greatly improves the computing time instead of memory consumption.

# **OPTION fact\_once file**

Save Cholesky factor of LHS in a temporary file. It improves the computing time without extra memory.

# OPTION approx\_loglike

Skip the exact computation of log-likelihood. It would improve the computing time.

# Heterogeneous residual variances for a single trait

#### **OPTION hetres** pos 10 11

Specify positions of covariables.

#### OPTION hetres pol 4.0 0.1 0.1

Initial values of coefficients for heterogeneous residual variances. Use ln(a0, a1, a2, ...) to make these values. When the number of positions = the number of polynomials, the regressions do not include the intercept (e.g., linear spline).

#### Heterogeneous residual variances for multiple traits (the convergence will be very slow)

#### **OPTION** hetres\_pos **10 10 11 11**

Specify positions of covariables (trait first).

# **OPTION** hetres\_pol 4.0 4.0 0.1 0.1 0.01 0.01

Initial values of coefficients for heterogeneous residual variances using ln(a0, a1, a2, ...) to make these values (trait first). "4.0 4.0" are intercept for first and second traits. "0.1 0.1" could be linear and "0.01 0.01" could be quadratic. To transform back to the original scale, use exp(a0+a1\*X1+a2\*X2).

#### **OPTION SNP\_file snp**

Specify the SNP file name snp to use genotype data.

# Standard deviations for (co)variance functions including heritability

#### **OPTION** se\_covar\_function label function

Calculate SD for (co)variance functions by repeated sampling of parameter estimates from their asymptotic multivariate normal distribution, following idea presented by Meyer and Houle 2013. For details, see documentation at http://nce.ads.uga.edu/wiki/doku.php?id=readme.aireml.

**GIBBSxF90** programs implement Bayesian methods. These methods potentially have better statistical properties. Also they are more stable and use less memory for complicated models. After running any of the Gibbs sampling programs, samples can be analyzed (posterior means, SD, and convergence parameters) with the POSTGIBBSF90 program.

In practical cases, results from Gibbs samplers and REML are similar. Choose one or the other based on computing feasibility. If there are large differences beyond sampling errors, this indicates problems usually with the Gibbs sampler. Try longer chains or different priors.

Gibbs samplers may be slow to achieve convergence if initial values are far away from those at convergence, e.g., 100 times too low or too high. Before using more complicated models, Karin Meyer advocates using a series of simpler models.

**GIBBS1F90** can run models with over 20 traits. However, if models are different per trait, the lines due to effects need to be modified. Also, with too many differences in models among traits, the program becomes increasingly slower.

**GIBBS2F90** adds joint sampling of correlated effects. This results in faster mixing with random regression and maternal models.

#### Interactive inputs:

#### number of samples and length of burn-in?

In the first run, if you have no idea about the number of samples and burn-in, just type your guess (10000 or whatever) for samples and (0) for burn-in. You may need 2 or 3 runs to figure out the convergence.

#### Give n to store every n-th sample?

Gibbs samples are highly correlated, so you do not have to keep all samples (every 10th, 20th, 50th, ...). The following options are available for **GIBBSxF90**:

# OPTION fixed\_var all 1 2 3

Store all solutions and posterior means and SD for effects for effects1, 2, and 3 are stored in "all\_solutions" and in "final\_solutions" every round using fixed variances. Without numbers, all solutions for all effects are stored.

# OPTION fixed\_var mean 1 2 3

Posterior means and SD for effects1, 2, and 3 in "final\_solutions".

#### **OPTION** solution all 1 2 3

Store all solutions and posterior means and SD for effects1, 2, and 3 are stored in "all\_solutions" and in "final\_solutions" every round. Without numbers, all solutions for all effects are stored.

# **OPTION** solution mean 1 2 3

Posterior means and SD for effects1, 2, and 3 in "final\_solutions".

#### **OPTION cont 10000**

10000 is the number of samples run previously when restarting the program from the last run.

# OPTION prior 5 2 -1 5

The (co)variance priors are specified in the parameter file. Degree of belief for all random effects should be specified using the following structure: OPTION prior eff1 db1 eff2 db2 ... effn dbn -1 dbres; where effx correspond to the effect number and dbx to the degree of belief for this random effect, -1 corresponds to the degree of belief of the residual variance. In this example 2 is the degree of belief for the 5th effect, and 5 is the degree of belief for the residual.

#### **OPTION seed 123 321**

Two seeds for a random number generator can be specified.

# **OPTION SNP\_file snp**

Specify the SNP file name **snp** to use genotype data.

**GIBBS3F90** adds estimation of heterogeneous residual covariances in classes. The computing costs usually increase with the number of classes.

#### **OPTION hetres\_int 5 10**

The position (5) to identify the interval in the data file and the number of intervals (10) for heterogeneous residual variances.

Other options are the same as for **GIBBS1F90** and **GIBBS2F90**. For **fixed\_var all** or **fixed\_var mean**, heterogeneous residual variances are read from a file 'hetres'. This file name can't be changed.

**THRGIBBS1F90** is a Gibbs sampling program to analyze categorical and continuous traits simultaneously; categorical traits can be censored. The following options are available:

#### OPTION cat 0 0 2 5

"0" indicate that the first and second traits are linear. "2" and "5" indicate that the third and fourth traits are categorical with 2 (binary) and 5 categories.

#### **OPTION thresholds 0.0 1.0 2.0**

Set the fixed thresholds. No need to set 0 for binary traits.

#### **OPTION** residual 1

Set the residual variance = 1.

# **OPTION** censored 10

Negative values of the last category in the data set indicate censored records. "1 0" determines that the first categorical trait is censored and the second categorical trait is uncensored.

Using following options for ordered categorical data with right censored records:

#### OPTION cat 0 0 2 5

#### **OPTION** censored 10

The data file may look like

traits:	1	2	3	4
	1.71	11.1	1	1
	2.22	15.2	0	5

3.29	16.4	2	1
1.95	14.7	1	3
2.25	20.8	-2	4
3.64	19.2	1	5
1.99	13.3	-1	2

Columns 1 and 2 are observations for linear traits and columns 3 and 4 are traits for 2 categories (binary) with censored records (negative values) and 5 categories.

Other options are the same as for GIBBS1F90 and GIBBS2F90.

**POSTGIBBSF90** is a program to calculate posterior means and SD and diagnose the convergence. The program reads "gibbs\_samples" and "fort.99" files from Gibbs sampling programs.

Read 1000 samples from round 10 to 10000

#### Burn-in?

# in the first run, type 0 for burn-in to include all samples

# Give n to read every n-th sample? (1 means read all samples)

# Type the same number used with a Gibbs sampling program. You shouldn't type 1 # unless you have typed 1 in the Gibbs sampling program.

# # samples after burn-in = 9000

Input files:

gibbs\_samples, fort.99, and other files used in a parameter file from (THR)GIBBSxF90 Output files:

postgibbs\_samples, postout, postmean, postsd

# postgibbs\_samples

A text file containing all Gibbs samples from **gibbs\_samples** for other software (EXCEL, SAS, ...) to calculate posterior means and SD, and to create graphs.

# postmean

Posterior means

### postsd

Posterior standard deviations

# postout

```
The distribution should be usually normal (Mean = Mode = Median).

print = 1; other graphs = 2; or stop = 0

0
```

```
*** Log Marginal Density for Bayes Factor ***
after 900 burn-in
log(p) = -179448.742766031
```

This value could be used when calculating Bayes Factor and/or DIC.

# **Genomic programs**

#### PREGSF90

The **PREGSF90** program constructs a genomic relationship matrix **G** and a relationship matrix  $\mathbf{A}_{22}$  for genotyped animals. The relationship matrix **A** based on the pedigree information in mixed model equations is replaced by matrix **H**, which combines the pedigree and genomic information. The main difference between  $\mathbf{A}^{-1}$  and  $\mathbf{H}^{-1}$  is the structure of  $\mathbf{G}^{-1} - \mathbf{A}_{22}^{-1}$ . Some of the options for **PREGSF90** can be also used with **BLUPF90**, (**AI**)**REMLF90**, **GIBBS1F90**, **GIBBS2F90**, **GIBBS3F90**, **THRGIBBS1F90**, and **BLUP90IOD2**.

#### *Input files*

# OPTION SNP\_file <file>

This option invokes the genomic routine in the application program. The SNP file should contain Field 1 - animal ID with the same format as in pedigree file

Field 2 - genotypes with 0, 1, 2, and 5 (missing) or real values for gene content (or genotype probability) 0.12. ...

Two Fields (animal ID and SNP) need to be separated by at least one space, and Field 2 should have fixed format (i.e., all rows of genotypes should start at the same column number or position).

8014 21110101511101120221110111511112101112210100

516 21100101202252021120210121102111202212111101

181 21110111112201120550200020101022212211111100
```

The renumbered ID file for genotypes named as the genotype file **name.XrefID** is created by RENUMF90 (using the SNP file), containing sequential ID renumbers and the original ID, which must be in the same order as in the SNP file as follows:

```
1732 80
8474 8014
406 516
9441 181
```

The pedigree file from RENUMF90 looks like

```
1732 11010 10584 1 3 12 1 0 0 80
8474 8691 9908 1 3 12 1 0 0 8014
406 8691 9825 1 3 12 1 0 2 516
9441 8691 8829 1 3 12 1 0 0 181
```

Map file for SNP can be used as optional:

**OPTION chrinfo <file>**: read SNP map information from the file.

```
Field 1 – SNP number (sequential marker number)
Field 2 – chromosome number
Field 3 – physical location (position) in bp
Example:

1 1 1201
```

```
2 1 8004
```

All the values should be integer. The SNP number corresponds to the index number of the SNP, in the sorted map by chromosome and the position. The first line in the file corresponds to the first SNP in the genotype file, and so on. You can optionally put the marker name in the 4<sup>th</sup> or later fields (can handle alphanumeric format). The map file is useful to check for Mendelian conflicts and HWE (with also OPTION sex\_chr) and for POSTGSF90 (ssGWAS).

With other options, the program can read  $\bf G$  or its inverse,  $\bf A_{22}$  or its inverse, etc.

#### Output files

By default, **PREGSf90** always create GimA22i in binary format for use by later programs specifying **OPTION readGimA22i**. With **OPTION saveAscii**, this file can be stored as ASCII format: i, j,  $\mathbf{G}^{-1} - \mathbf{A}_{22}^{-1}$ . "freqdata.count" contains allele frequencies in the original genotype file with the format: SNP number (related to the genotype file) and allele frequency as mentioned above.

"freqdata.count.after.clean" contains allele frequencies as used in calculations with the format: SNP number (related to the genotype file), allele frequency, and code of exclusion.

#### **Exclusion codes:**

- 1: Call Rate
- 2: MAF
- 3: Monomorphic
- 4: Excluded by request
- 5: Mendelian error
- 6: HWE
- 7: High Correlation with other(s) SNP

"Gen call rate" contains a list of animals excluded with call rate below the threshold.

"Gen\_conflicts" contains a report of animals with Mendelian conflicts with their parents.

The program can store files such as G or its inverse,  $A_{22}$  or its inverse, or other reports from QC as specified by their respective OPTIONs.

Options for creation of genomic relationship Matrix (G)

The genomic relationship matrix G can be created in different ways.

#### **OPTION** which G x

Specify how **G** is created.

The variable x can be

1: 
$$G = \frac{ZZ'}{k}$$
; VanRaden, 2008 (default)

2: 
$$G = \frac{ZDZ'}{n}$$
; Amin et al., 2007; Leuttenger et al., 2003; where  $\mathbf{p} = \frac{1}{2p(1-p)}$ 

3: As 2 with modification UAR from Yang et al 2010

<sup>3 1 12006</sup> 

# **OPTION** whichfreq x

Specify what frequency is used to create **G**.

The variable x can be

0: read from file "freqdata" or from the other file using OPTION FreqFile

1:0.5

2: current calculated from genotypes (default)

# **OPTION FreqFile <file>**

Read allele frequencies from a file. For example, based on allele frequencies calculated by estfreq.f90 (VanRaden, 2009) with format:

Field 1 – SNP number (sequential marker number)

Field 2 - allele frequency as a real value from 0 to 1

Example:

- 1 0.525333
- 2 0.293667
- 3 0.448333
- 4 0.510667

where SNP corresponds to the index of SNP based on the same order that are in the genotype file. If whichfreq is set to 0, the default file name is "freqdata".

### **OPTION** which Scale x

Specify how **G** is scaled.

The variable x can be

1: 
$$2\sum \{p(1-p)\}$$
; VanRaden 2008 (default)

2: 
$$\frac{tr(ZZ')}{n}$$
; Legarra 2009, Hayes 2009

3: correction; Gianola et al 2009

# **OPTION weightedG <file>**

Read weights from a file to create weighted genomic relationship. Weighting  $Z^* = Z \cdot T^* = ZDZ'$ . Format:

Field 1 - weight

Example:

- 0.7837836E-01
- 0.4900770E-01
- 0.7538282
- 1.0

Each weight is corresponding to each SNP marker defied in the map file.

Weights can be extracted from output of the POSTGSF90 program.

#### **OPTION** maxsnp x

Set the maximum length of string to read marker data from a file. It is only necessary if greater than default (400,000).

# Quality Control (QC) for G

By default the following QC can be run:

MAF

Call rate (SNPs and animals)

Monomorphic

Parent-progeny conflicts (SNPs and animals)

Parameters can be modified with the following options:

#### **OPTION** minfreq x

Ignore all SNP with MAF < x (default value = 0.05).

#### **OPTION** callrate x

Ignore SNP with call rates < x (number of calls / number of individuals with genotypes). The default value is 0.90.

#### **OPTION** callrateAnim x

Ignore genotypes with call rates < x (number of calls / number of SNPs). Default value is 0.90.

#### **OPTION** monomorphic **x**

Ignore monomorphic SNPs. Optional parameter  $\mathbf{x}$  can be used to enable (1) or disable (0) the check, default value 1.

# **OPTION** hwe x

Check departure of heterozygous from Hardy-Weinberg equilibrium. By default this QC is not run. The optional parameter  $\mathbf{x}$  can be the maximum difference between observed and expected frequency (default value = 0.15) as used in Wiggans et al. (2009) in JDS.

#### **OPTION** high\_correlation x y

Check for high correlated SNP. By default this QC is not run. The optional parameter  $\mathbf{x}$  can be the maximum difference in allele frequency to check a pair of locus. If no value is set, 0.025 is used. Decrease this value to speed up the calculation. A pair of loci is considered highly correlated if all genotypes are the same (0-0, 1-1, 2-2) or the opposite (0-2, 1-1, 2-0) (Wiggans et al., 2009. JDS). The optional parameter  $\mathbf{y}$  can be used to set a threshold to check the number of identical samples out of the number of genotypes (default values:  $\mathbf{x}$ =0.025,  $\mathbf{y}$ =0.995).

# **OPTION** verify\_parentage x

Verify parent-progeny Mendelian conflicts and write report to a file "Gen\_conflicts". The optional parameter x can be

0: no action

- 1: only detect
- 2: detect and search for an alternate parent; no change to any file. Not yet implemented
- 3: detect and eliminate progenies with conflicts (default)

# OPTION exclusion\_threshold x

Set the number of parent-progeny exclusions as percentage. All SNP are used to determine wrong relationships (default value = 2).

#### OPTION exclusion threshold snp x

Set the number of parent-progeny exclusions for each locus as percentage. A pair of genotyped animals is evaluated to exclude SNP from the analysis (default value = 10).

# **OPTION** number\_parent\_progeny\_evaluations x

Set the number of minimum pair of parent-progeny evaluations to exclude SNP due to parent-progeny exclusion (default value = 100).

### **OPTION** outparent\_progeny x

Create a full log file "Gen\_conflicts\_all" with all pairs of parent-progeny tested for Mendelian conflicts.

# OPTION excludeCHR n1 n2 n3 ...

Exclude all SNP from chromosomes n1, n2, n3, ... A map file must be provided (see OPTION chrinfo).

#### OPTION sex\_chr n

Set the chromosome number equal to or greater than  $\mathbf{n}$  are not considered autosome. If this option is used, sex chromosomes will not be used for checking parent-progeny, Mendelian conflicts, and HWE. A map file must be provided (see **OPTION chrinfo**).

# **OPTION** threshold\_duplicate\_samples x

Set the threshold to issue warning for possible duplicate samples if G(i,j) / sqrt(G(i,i) \* G(j,j)) > x (default value = 0.9).

# OPTION threshold\_diagonal\_g x

Check for extremely large diagonals in the genomic relationship matrix. If optional  $\mathbf{x}$  is present, the threshold will be set (default value = 1.6).

# **OPTION plotpca**

Plot first two principal components to look for stratification in the population.

#### OPTION extra info pca <file> col

Read the column col to plot with different colors for different classes from the file. The file should contain at least one variable with different classes for each genotyped individual, and the order should match the order of the genotype file. Variables could be alphanumeric and separated by one or more spaces.

#### **OPTION saveCleanSNPs** \*

Save clean genotype data with excluded SNP and animals based on the OPTIONS specified.

- \*\_clean files are created:
- gt clean
- gt\_clean\_XrefID
- \*\_removed files are created.
- gt\_SNPs\_removed
- gt Animals removed

where "gt" is the genotype file.

# **OPTION no\_quality\_control**

Turns off all quality control. It is useful to speed up computation when the QC was performed previously.

#### **OPTION** outcallrate

Print all call rate information for SNP and individuals. The files "callrate" for SNP and "callrate\_a" for individuals are created.

Quality Control for Off-diagonal of  $A_{22}$  and G

# **OPTION thrWarnCorAG x**

Set the threshold to issue warning if correlation between  $A_{22}$  and G < x (default value = 0.5).

#### **OPTION thrStopCorAG x**

Set the threshold to stop the analysis if correlation between  $A_{22}$  and G < x (default values = 0.3).

#### **OPTION thrCorAG x**

Set the threshold to calculate correlation between  $A_{22}$  and G for only  $A_{22} \ge x$  (default values = 0.02).

# Options for **H**

The options includes different weights to create  $\mathbf{G}^{-1} - \mathbf{A}_{22}^{-1}$  as

$$\tau(\alpha \mathbf{G} + \beta \mathbf{A}_{22} + \gamma \mathbf{I} + \delta \mathbf{1} \mathbf{1}')^{-1} - \omega \mathbf{A}_{22}^{-1}$$

where the parameters are to scale the genomic info to be compatible with the pedigree information, to make matrices invertible in the presence of clones, and to control bias. The defaults values are: tau  $(\tau)$  = 1, alpha  $(\alpha)$  = 0.95, beta  $(\beta)$  = 0.05, gamma  $(\gamma)$  = 0, delta  $(\delta)$  = 0 and omega  $(\omega)$  = 1. Options to change these defaults are specified with:

**OPTION TauOmega tau omega** 

**OPTION AlphaBeta alpha beta** 

**OPTION GammaDelta gamma delta** 

#### **OPTION** tuned**G** x

Scale **G** based on **A**<sub>22</sub>. The variable **x** can be:

0: no scaling

1: mean(diag(G))=1 and mean(offdiag(G))=0

2:  $mean(diag(G))=mean(diag(A_{22}))$  and  $mean(offdiag(G))=mean(offdiag(A_{22}))$  (default)

3:  $mean(G)=mean(A_{22})$ 

4: rescale **G** using the first adjustment as in Powell et al. (2010) or Vitezica et al. (2011).

# General control of PREGSF90

#### **OPTION** nthreads n

Specify number of threads to be used with MKL-OpenMP for creation and inversion of matrices.

#### **OPTION** ntheadsiod n

Specify number of threads to be used with MKL-OpenMP in BLUP90IOD for matrix-vector multiplications in the PCG algorithm.

#### **OPTION** graphics s

Allows to generate plots with GNUPLOT. If optional parameter s is present, set the time in seconds to show the plot. Avoid using in batch programs!!!

#### **OPTION** msg x

Set the level of verbose; 0 minimal; 1 gives lots of diagnostics.

# Save and Read options:

#### **OPTION saveAscii**

Save intermediate matrices (GimA22i, G, Gi, etc.) files as ASCII (default = binary).

#### **OPTION** saveHinv

Save H-1 in "Hinv.txt" (format: i, j, val with i, j, the index level for the additive genetic effect).

#### **OPTION** saveAinv

Save A in "Ainv.txt" (format: i, j, val with i, j, the index level for the additive genetic effect).

The following options use the information of the original ID (alphanumeric) stored in the 10th column of the "renaddxx.ped" file created by **RENUMF90**.

# **OPTION saveHinvOrig**

Save H-1 with original IDs

#### **OPTION saveAinvOrig**

Save **A**<sup>-1</sup> with original IDs

# **OPTION** saveDiagGOrig

Save diagonal of G in "DiagGOrig.txt" (format: id, val with id, original IDs).

#### **OPTION** saveGOrig

Save **G** in "G Orig.txt" (format: id i, id j, val with id i and id j, the original IDs).

#### **OPTION saveA22Orig**

Save A<sub>22</sub> in "A22 Orig.txt" (format: id i, id j, val with id i and id j, the original IDs).

# **OPTION readOrigId**

Read information from "renaddxx.ped" file, original ID and possibly year of birth for its use in parent-progeny conflict. Only need unless the previous "save\*Orig" is present.

#### **OPTION savePLINK**

Save genotypes in PLINK format files: toPLINK.ped and toPLINK.map.

Save and Read intermediate files:

#### OPTION readGimA22i <file>

Read  $\tau G^{-1} - \omega A_{22}^{-1}$  from a file. This option can be used in analysis programs (BLUPF90, REMLF90, etc.) in order to use matrices stored in GimA22i file (default filename). In general, methods used to create and invert matrices in such programs don not use optimized version. For large number of genotyped animals, run first PREGSf90 and read stored matrices in analysis programs.

The optional file can be used to specify the other file name or path.

For example,

# **OPTION readGimA22i** ../../pregsrun/GimA22i

Other intermediate matrices files can be stored for inspection or for use in BLUPF90 programs as **user\_file** type of random effect. See **tricks** and **REMLF90** for details.

Individual output options:

#### **OPTION saveA22**

Save  $A_{22}$  in "A22".

#### **OPTION saveA22Inverse**

Save  $\omega A_{22}^{-1}$  in "A22i".

# **OPTION saveG all**

If optional all is present, all intermediate matrices for **G** will be saved in separate files. If omitting all, only the final **G** will be saved in "G".

#### **OPTION** saveGInverse

Save  $\tau \mathbf{G}^{-1}$  in "Gi".

# **OPTION saveGmA22**

Save  $\mathbf{G} - \mathbf{A}_{22}$  in "GmA22". This option is obsolete.

#### **OPTION readG <file>**

Read **G** from "G" by default, or from user-supplied **file**.

#### **OPTION readGInverse <file>**

Read  $G^{-1}$  from "Gi" by default, or from user-supplied file. See the caution below.

#### OPTION readA22 <file>

Read  $A_{22}$  from "A22" by default, or from user-supplied file.

#### OPTION readA22Inverse <file>

Read  $A_{22}^{-1}$  from "A22i" by default, or from user-supplied file. See the caution below.

#### OPTION readGmA22 <file>

Read  $G - A_{22}$  from "A22i" by default, or from user-supplied file. This option is obsolete.

#### Caution:

With the options readGinverse and readA22Inverse, the program applies  $\tau$  to the loaded  $G^{-1}$  and  $\omega$  tor the loaded  $A_{22}^{-1}$  regardless of whether the matrices have been already scaled with  $\tau$  or  $\omega$ . In other words, the loaded matrix could be scaled twice if the user used  $\tau$  or  $\omega$  both in saving and reading the matrix. Be careful to use the scaling factors combined with the input/output options.

# POSTGSF90

# Basic options

The program calculates SNP effects using the ssGBLUP framework (Wang et al., 2012). The program needs **OPTION chrinfo** to calculate SNP effects. The following options for **POSTGSF90** (ssGWAS) are available:

#### **OPTION Manhattan\_plot**

Plot using **GNUPLOT** the Manhattan plot (SNP effects) for each trait and correlated effect.

#### **OPTION Manhattan\_plot\_R**

Plot the Manhattan plot (SNP effects) for each trait and correlated effects using R. TIF images are created: manplot\_Sft1e2.tif (note: t1e2 corresponds to trait 1, effect 2). **CAIRO** packaged is required.

#### **OPTION plotsnp n**

Control the values of SNP effects to use in Manhattan plots

1: plot regular SNP effects: abs(val)

2: plot standardized SNP effects: abs(val/sd) (default)

#### **OPTION SNP\_moving\_average n**

Solutions for SNP effects will be by moving average of n adjacent SNPs.

# **OPTION windows\_variance n**

Calculates the variance explained by n adjacent SNPs.

# **OPTION** windows\_variance\_mbp n

Calculates the variance explained by n Mb window of adjacent SNPs.

# **OPTION windows\_variance\_type n**

Sets windows type for variances calculations

1: moving windows

2: exclusive windows

# **OPTION** which\_weight x

Generates a weight variable to be used in the creation of a weighted genomic relationship matrix  ${f G}=$ 

# ZDZ'

1: scaled  $w_i = \hat{u}_i^2 [2p_i(1-p_i)] \times k$ 

2: scaled  $w_i = \hat{u}_i^2 \times k$ 

where  $k = n / \sum_{i=1}^{n} w_i$  as the scaling factor and n is the number of markers.

# **OPTION solutions\_postGS x**

Sets the file name for the solutions file, default solutions

# OPTION postgs\_trt\_eff x1 x2

Computes postGS calculations (SNP solutions, variance explained, etc.) for only trait: x1 and effect: x2

# **OPTION** snp\_effect\_gebv

Computes SNP effects from GEBV instead of DGV

Default

#### OPTION snp\_effect\_dgv

Computes SNP effects from DGV instead of GEBV

# Output files for **POSTGSF90**:

"snp\_sol" contains solutions of SNP and weights

- 1: trait
- 2: effect
- 3: SNP
- 4: Chromosome
- 5: Position
- 6: SNP solution
- 7: weight (can be used as the weight to calculate the weighted **G** matrix) #if **OPTION windows\_variance** is used
- 8: variance explained by n adjacent SNP.

"chrsnp" contains data to create plot by GNUPLOT

- 1: trait
- 2: effect
- 3: values of SNP effects to use in Manhattan plots

```
4: SNP
```

- 5: Chromosome
- 6: Position

"chrsnpvar" contains data to create plot by GNUPLOT

- 1: trait
- 2: effect
- 3: variance explained by n adjacent SNP
- 4: SNP
- 5: Chromosome
- 6: Position

"dgv" contains direct genomic values (DGV) and pedigree predictions (PP).

- 1: trait
- 2: effect
- 3: animal ID
- 4: DGV =  $-\sum_{i\neq i}^{n} g^{ij} GEBV_i/g^{ii}$  where  $g^{ij}$  is the elements in  $\mathbf{G}^{-1}$ . See Lourenco et al. (2015).
- 5: PP =  $-\sum_{i\neq i}^{n} a_{22}^{ij} GEBV_j/a_{22}^{ii}$  where  $a_{22}^{ij}$  is the elements in  $\mathbf{A}_{22}^{-1}$ . See Lourenco et al. (2015).

"snp\_pred" contains gene frequencies + SNP effects. The file is needed for PREDF90 to indirectly calculate GEBV for animals based on the SNP effects i.e.  $\hat{\mathbf{a}} = \mathbf{Z}\hat{\mathbf{u}}$ .

#### *Graphic control files:*

Several files are created to generate graphics using either GNUPLOT or R.

#### File names rules

"Sft1e2.R". The first letter indicates "S" for solutions of SNP and "V" for variance explained. "t1e2" indicates that the file is for the trait 1 and the effect 2.

#### Filename extension

```
xxx.gnuplot => GNUPLOT
xxx.R => R programs
xxx.tif => image
```

# PREDF90

Predicts direct genomic value (DGV) for young animals based on only genotypes i.e.  $\hat{\mathbf{a}} = \mathbf{Z}\hat{\mathbf{u}}$ , where  $\hat{\mathbf{a}}$  is DGV and  $\hat{\mathbf{u}}$  is the SNP effects. The prediction is based on SNP effects obtained from **POSTGSF90**. For young animals that were not included in the previous analysis, DGV can be calculated using the "snp\_pred" file from **POSTGSF90**. This program simply asks the user about the name of genotype file.

# Input files:

This program automatically detects and read the following file.

# "snp\_pred"

- information about the random effect (number of traits + correlated effects)
- gene frequencies
- solutions of SNP effects

# Snp\_file\_for\_animals\_to\_predict

SNP file for animals to have DGV predicted. This file has the same format as used in PREGSf90 and POSTGSf90.

# Output file:

"SNP predictions"

- ID, calling rate, and DGV

Constant parameters that cannot be changed by the users:

- 1. alpha fraction of G used (default=0.95); affects scale of prediction
- 2. callrate to be used later for discarding genotypes with poor quality (default=0.7)

  PREDICTF90 1.3
                    2
Animal Effect:
y(s), yhat(s), residual(s) in written in "yhat_residual" file
Trait:
            1 15800
  mean Y
               4.03501847757689
                                      var Y
                                                 83.7152229825781
                 4.03446550045574
                                                     32.2906703880498
  mean Yhat
                                        var Yhat
```

```
cov (Y,Yhat) 47.5001153783459 corr (Y,Yhat) 0.913595421845247
```

wrote bvs for animals in data in file "bvs.dat"

#### Hints:

1) The effect that goes into OPTION include\_effects (e.g., OPTION include\_effects 2) is included in the Yhat. In this small example with 1 trait, the format of yhat\_residual is:

```
Animal_id, Y, Yhat, residual where: Y = Phenotype - \mu Y = EBV (or animal effect) Residual = Phenotype - EBV
```

2) When 2 traits are used in the model, the format of yhat\_residual is:

```
Animal_id, Y1, Y2, Yhat1, Yhat2, residual1, residual2
```

3) corr (Y,Yhat) should not be used as a measure of predictivity because it uses adjusted phenotypes and EBVs from the same dataset. Usually, predictivity requires phenotypes adjusted for fixed effects in the complete data (benchmark) and (G)EBVs calculated from the reduced data (without records for validation animals). The regular predictivity measure is: corr[Y\_from\_PREDICTf90, (G)EBV\_reduced]

For this small example with 1 trait, a general linux code is:

```
$awk '{print $1,$2}' ebv_complete/yhat_residual | sort +0 -1 > Y
$awk '{if ($2==2) print $3,$4}' ebv_reduced/solutions | sort +0 -1 >
ebv.temp
$awk '{if ($2==2) print $3,$4}' gebv_reduced/solutions | sort +0 -1 >
gebv.temp
$join -1 +1 -2 +1 Y validation_animals > file1.temp
$join -1 +1 -2 +1 file1.temp ebv.temp > file2.temp
$join -1 +1 -2 +1 file2.temp gebv.temp > Y ebv gebv
```

#obs: validation\_animals is a file that contains sorted ids for validation animals

```
An R code to calculate correlations is:

pred <- read.table("Y_ebv_gebv",header=F)

ebv_predictivity <- cor(pred[,2],pred[,3]); ebv_predictivity

gebv_predictivity <- cor(pred[,2],pred[,4]); gebv_predictivity
```

# Appendix A (single trait animal model)

Single trait "USDA-type" animal model. This example is from the documentation of program JAA20.

```
y_{ijkl} = hys_i + hs_{ij} + p_k + a_k + e_{ijkl}
```

#### where

y<sub>ijkl</sub> - production yield

hysi - fixed herd year season

hs<sub>ii</sub> - random herd x sire interaction

p<sub>k</sub>- random permanent environment

a<sub>k</sub> - random animal

and

$$var(hs_{ij}) = .05, var(p_k) = .1, var(a_k) = .5, var(e_{ijkl}) = 1$$

## Appendix D (multibreed maternal effect model)

This model was used for studies on multibreed evaluation in beef cattle. It is provided as an example of a model with maternal effect and different models per trait.

```
Model (in concise form, with most indices omitted)
```

```
y_1=cg_1 + bt + mbt + a + M + e

y_2=cg_2 + bt + mbt + a + M + pe + e

y_3=cg_3 + bt + mbt + a + e
```

#### where

```
y_{1-3} - birth weight, weaning weight, and gain cg_{1-3} - contemporary groups separate for each trait br - breed type mbt - maternal breed type a - additive effect brack m - maternal effect brack pe - permanent environmental effect of the dam
```

## Data file (data.out)

# Appendix E (random regression model)

A single-trait random regression model for test-day milk is using cubic Legendre polynomials.

Model

$$y_{ijkl} = hym_{ij} + \sum_{m=1}^{4} \alpha_m(l)h_{im} + \sum_{m=1}^{4} \alpha_m(l)u_{km} + \sum_{m=1}^{4} \alpha_m(l)pe_{im} + e_{ijkl}$$

where

y<sub>ijkl</sub> - test day milk

hym<sub>ii</sub> - hear-year-test for herd i and year-test j

h<sub>i</sub> - effects of herd i

 $\alpha_m(I)$  - value of m-th Legendre polynomial at point corresponding to DIM=I

u - additive effects

pe - permanent environmental effects

## Data file (datarr)

Format:

# Appendix I (complete genomic analysis)

Data files are available at http://nce.ads.uga.edu/wiki/doku.php?id=course\_materials\_-\_from\_uga\_2014.

Using RENUMF90, PREGSF90, BLUPF90 (BLUP), BLUPF90 (ssGBLUP), PREDICTF90, POSTGSF90 (ssGWAS)

#### Simulated data

Single trait with heritability of 0.30 and phenotypic variance = 1.0

Five generations

Total of 994 parents from generations 1 to 4 were genotyped

Three hundred progeny from 5<sup>th</sup> generation had genotypes and pedigree, but phenotypes were removed for traditional and genomic evaluations

#### Data Structure:

### Solutions for BLUPF90 without genomic information

```
    1
    2
    2
    0.16420973

    1
    2
    3
    0.32371581

    1
    2
    4
    0.00318130

    1
    2
    5
    -0.13277100
```

The solution file (solutions) has 4 columns:

- 1) Trait [only 1 trait in this example]
- 2) Effect [we have 2 effects: overall mean (effect 1) and additive genetic direct (effect 2)]
- 3) Level [number of the level for each effect in the model]
- 4) Solution

## **EBV** accuracy

If accuracy of EBV is desired, it can be calculated based on standard errors (se) for EBV.

**BLUPF90** has an option for calculating se:

#### **OPTION** sol se

## Solutions for BLUPF90 with option to calculate se

trait	/effect	level	solution	s.e.
1	1	1	1.02176504	0.02496866
1	2	1	-0.24665117	0.39158195
1	2	2	0.16421026	0.40488662
1	2	3	0.32371755	0.29405286
1	2	4	0.00318218	0.38229658
1	2	5	-0.13277154	0.46566701

The solution file now includes a 5<sup>th</sup> column with EBV standard errors

#### Solutions for BLUPF90 with genomic information (ssGBLUP)

The solution file has the same format as in blupf90 without genomic information. The option for calculating se for EBV can also be used here.

#### **Parameter file for PREDICTF90**

Predictivity can be measured as correlation between adjusted phenotypes and (G)EBV. In this example we show how to use PREDICTF90 to adjust phenotypes for genotyped animals in the validation population.

#### 1) Adjusting phenotypes

As this program needs solution file, it can be run in the same folder as BLUP with complete data

Parameter file:

DATAFILE
pred.dat

NUMBER\_OF\_TRAITS

1

NUMBER\_OF\_EFFECTS

2

OBSERVATION(S)

1

WEIGHT(S)

pred.dat is the data file only for genotyped animals in 5<sup>th</sup> generation (validation animals). Lines can be extracted from renf90.dat

```

#### **Output files from PREDICTF90**

#### yhat\_residual

```
yhat_residual has 4 columns: animal | y | yhat | residual
```

```
    4644
    -0.266520
    0.415535
    0.339710

    2176
    -0.418925
    0.094263
    0.508577
```

#### bvs.dat

y is phenotype minus all effects other than animal yhat receives the second effect, which is the animal effect residual is phenotype minus animal effect

Because OPTION include\_effects 2 was used:

```
bvs.dat has 4 columns: trait | effect | Animal | solution (EBV)
```

```
1 2 4644 0.415535
1 2 2176 0.094263
```

Hint: corr (Y,Yhat) from the output of PREDICTF90 (corr (Y,Yhat) 0.306765659847626) should not be used as a measure of predictivity because it uses adjusted phenotypes and EBVs from the same dataset. Usually, predictivity requires phenotypes adjusted for fixed effects in the complete data (benchmark) and (G)EBVs calculated from the reduced data (without records for validation animals). The regular predictivity measure is: corr[Y\_from\_PREDICTf90, (G)EBV\_reduced]

#### For this small example with 1 trait, a general linux code to merge files is:

```
$awk '{print $1,$2}' ebv_complete/yhat_residual | sort +0 -1 > Y
$awk '{if ($2==2) print $3,$4}' ebv_reduced/solutions | sort +0 -1 >
ebv.temp
$awk '{if ($2==2) print $3,$4}' gebv_reduced/solutions | sort +0 -1 >
gebv.temp
$join -1 +1 -2 +1 Y ebv.temp > file1.temp
$join -1 +1 -2 +1 file1.temp gebv.temp > Y ebv gebv
```

#### An R code to calculate correlations is:

```
pred <- read.table("Y_ebv_gebv",header=F)
ebv_predictivity <- cor(pred[,2],pred[,3]); ebv_predictivity
gebv_predictivity <- cor(pred[,2],pred[,4]); gebv_predictivity</pre>
```

This file is used by POSTGSF90 for Manhattan plots

# Appendix J (custom relationship matrices)

When a relationship (or dispersion) matrix cannot be created within the application programs, it can be prepared separately and then included as a custom relationship matrix. Two options exist for inclusion of such a matrix. Option user\_file incorporates this matrix directly. Option user\_file\_inv incorporates the inverse of this matrix.

The example below presents a model from the previous Appendix with matrix **H**<sup>-1</sup> created externally and then read as a custom matrix. The custom matrix (Hinverse.txt) is stored as below, with each line containing: row, column and value.

```
1 1 3.0000

1 422 -1.0000

1 870 0.5000

1 4326 -1.0000

1 4612 -1.0000

. . . .

6096 6100 -0.0527

6097 6097 2.5000

6098 6098 11.0000

6099 6099 2.0000

6100 6100 12.0236
```

## **Modules and Libraries**

#### **Module DENSEOP**

Subroutines and functions for dense matrix manipulation in Fortran 90.

Uses F90 LAPACK implementation by Alan Miller for some low level routines.

Written by: Tomasz Strabel & Ignacy Misztal, University of Georgia e-mail:

strabel@au.poznan.pl, ignacy@uga.edu, Oct/5/98-June 8,

2006

The module implements matrix operations on dense general and symmetric matrices. Each subroutine/function is overloaded to work with several types of arguments. The module is primarily designed for matrix operations where timing and memory requirements are not critical.

#### **Symmetric matrices**

Each of the functions/subroutines works with full-stored and packed (half-stored) matrices. Each matrix or vector can be single or double precision. However, in one function/subroutine, all arguments should be of the same precision, and all matrices should be stored the same way.

#### **Subroutines**

```
call chol(a,rank) - Cholesky decomposition
call inverse_s(A,rank) - Generalized inverse: AI = A-
call eigen(A,d,V) - Eigenvalues and eigenvectors: A = V diag(d)*V'
call solve_s(A,b,x) - Generalized solutions: x: Ax=b
```

The optional variable rank returns the rank of the matrix.

# Functions

```
fchol(A) - Cholesky decomposition
finverse_s(A) - Generalized inverse
fsolve_s(A,b) - Generalized solve
fdet s(A) - Determinant of A
```

Procedures for symmetric matrices work with generalized matrices. Redundant rows/columns equations are determined by operational zero, which is kept in global variable denseop\_tol with default value is 10-10. To change the limit, change the value of the variable in the application program, e.g., denseop\_tol=1d-12

## Conversions

Let A be a square matrix and AP be a packed matrix

```
call packit (A, AP) - Conversion from square to packed form; only lower-diagonal elements are used.
```

call unpackit (AP, A) - Conversion from packed to square form; the matrix is assumed symmetric.

#### **General matrices**

Each matrix or vector can be single or double precision. However, in one function/subroutine, all arguments should be of the same precision. All matrices are assumed full-rank.

## Subroutines

```
call inverse(A) - Inverse: AI = A-1 call solve(A,b,x) - Solutions: x: Ax=b
```

#### **Functions**

```
AI=finverse(A) - Returns inverse: AI = Ax=fsolve(A,b) - Computes solutions: x: Ax=b
```

## Printing

call printmat (matrix, text, fmt, un) print any type of matrix using the specified format fmt and preceded by text. Both text and fmt are optional. If optional un is present, the output is send to file with unit un.

Warning: The printmat function prints the symmetric packed matrices in full. If a half-stored matrix is in packed form, it will be printed as full-stored matrix.

## Additional subroutines and functions

The subroutine(s) and functions below work only with double precision arguments (r8) and fullstored matrices.

```
call pos_def(x, text, min_eig, stat) Corrects X if it is not "sufficiently" positive-definite; ignores rows/columns with 0 elements only.
```

X - real (r8) symmetric square matrix

text - optional character variable that is printed if X is corrected

min\_eig - optional real (r8) variable that sets the minimum relative eigenvalue in X; if min\_eig is missing, 1e-5 is used.

stat - optional logical variable that is set to .true. if X was corrected and .false. if not.

A = diag(b) - creates square diagonal real (r8) matrix with values of real (r8) vector b on diagonal

```
b = diag(A) - creates real (r8) vector b containing diagonals of real (r8) matrix A

A=kron(B,C) - A = B "Kronecker product" C; works with real(r4) and real (r8) matrices
```

#### **Technical details**

The basic operations are done in full storage and double precision. Operations with other formats and precision are obtained by conversions. Computing of eigenvalues/eignevectors and general matrix operations use parts of LAPACK subroutines as converted by Alan Miller. These subroutines may contain many more functionality than necessary and may be trimmed to reduce size of the object code.

The modules consist of two files:

lapack90r.f90 - Part of LAPACK denseop.f90 - Interfaces, subroutines, functions and conversion codes.

For compilation, module kind in file kind.f90 that contains definitions of single and double precision is also needed.

In the BLUPF90 distribution, these files are included in directory libs and are compiled as denseop.a. One way to use the denseop module is via a Makefile from an application program in the blupf90 package.

## Example (exdense.f90)

#### Program Example:

```
use kinds; use denseop
real (r4):: xpacked4(3)=(/1,3,10/) ! Symmetric packed single
precision
real (r4)::x4(2,2) ! Full single precision
real (r8)::x8(2,2) ! Full double precision
call printmat(xpacked4,' X ')
call printmat(fchol(xpacked4),' Cholesky(X) ','(10(f10.2))')
x4=xpacked4
x8=x4
print*,' Determinant(xpacked4)=',fdet_s(xpacked4)
print*,' Determinant(x8)=',fdet_s(x8)
print*,' Determinant(x4)=',fdet_s(x4)
end
```

#### **Compilation**

To compile standalone:

```
f90 kind.f90 lapack90r.f90 denseop.f90 exdense.f90
```

This assumes that all files are in the same directory.

To compile in subdirectory of the blupf90 distribution under Linux/Absoft,

```
f90 -p ../libs exdense.f90 ../libs/denseop.a
```

where option -p specifies library directory. This option (-p) is different under different platforms. See documentation on blupf90 distribution for details.

#### **Module SPARSEM**

Collection of sparse matrix modules for Fortran 90 useful in animal breeding problems

Written by: Ignacy Misztal, University of Georgia e-mail: ignacy@uga.edu,

9/4/1997 - 5/25/2007

#### Introduction

Traditionally, programming in animal breeding is done in 2 stages: in a matrix language and in a regular programming language. Programs in a matrix language such as IML SAS, Matlab, Mathematica or APL are reasonably simple and useful for creating examples but inefficient for large problems. Programs in a regular programming language such as Fortran or C/C++ are much more efficient but could take much longer to write and require substantial training.

Matrix languages are easy to deal with matrices partly because usually only one format is usually supported: dense rectangular. Operations on such matrices are easy to specify and program, but large matrices require large memory and long running time. Also, memory and computations are equal whether matrices are sparse (contain very few nonzero elements) or not. In animal breeding, many matrices are sparse. If that sparsity is taken into account, the memory requirements and computations can decrease dramatically. Unfortunately, there is more than one format for storing sparse matrices, and some computations are fast with one format and but not with another one. Also, the storage formats and operations are considerably more complicated than dense rectangular matrices. A library to handle multiple matrix formats and multiple operations would contain many subroutines, each with a long list of arguments. Such a library would involve considerable learning, and many details associated with the library would create many opportunities for making a mistake.

One matrix package, Matlab, has some forms of sparse-matrix storage and operations included.

Modern programming languages with "object-oriented" features, such as C++ or Fortran 90, have abilities to create classes/modules, where many implementation details on specific data structures can be hidden. A technique called overloading allows single function/subroutine to work with different formats of its arguments. Therefore, the number of details to remember can be drastically reduced. Subsequently, programming can be done much easier and quicker.

SPARSEM is a module for Fortran 90 that enables programming common sparse matrix operations almost as easily as with dense matrices. It supports two dense matrix formats, useful for testing, and two sparse matrix formats. Changing a program from dense to sparse-matrix format using DENSEM can be as simple as changing one declaration line. SPARSEM incorporates an interface to FSPAK, which enables efficient sparse matrix factorization, solving, sparse inversion and calculation of determinant on matrices much larger than possible with dense matrix structures.

#### **Matrix formats**

Four matrix formats are available.

DENSEM - dense square matrix.

DENSE\_SYMM -dense symmetric upper-stored.

It has approximately only half memory requirements of the dense square matrix.

SPARSE\_HASHM - sparse triple accessed by hash algorithm.

This is a very efficient format for set-up and for iterative-solving of sparse matrices. SPARSE\_IJA - Sparse IJA.

This is a memory-efficient format for sparse matrices used by sparse matrix packages. Format IJA cannot easily be set up directly but can be derived by conversion from the hash format.

For more information on all these formats see Duff et al, George and Liu, or my class notes.

A popular format that is not included here is linked list. That format is reasonably efficient for creating and computing with sparse matrices if the number of nonzero elements per row is not too high and the matrix is not too large. However, the combination of hash plus ija is generally more efficient.

## **Matrix operations**

The following subroutines/functions are supported. All real scalars and vectors are single precision unless indicated otherwise.

Operation	Description	Comments
call init(x)	Initialize x	Required by standard but usually not necessary because on most systems pointers are initialized automatically
call zerom(x,n)	Allocate storage for x as an n*n matrix and zero it	If x was set before, it is reallocated <sup>1</sup>
call reset(x)	Deallocates storage	
call addm(a,i,j,x)	Add to matrix: x(i,j)=x(i,j)+a	Does not work on SPARSE_IJA
call setm(a,i,j,x)	sets element of matrix: x(i,j)=a	Does not work on SPARSE_IJA

y=getm(i,j,x)	find element of matrix: y=x(I,j)	real(4) function; returns lower- diagonal elements of upper- stored matrix
x=y	Conversion between formats	Conversion from sparse to dense formats may require too much storage
call printm(x)	Prints x as square matrix	print(x,'internal') prints sparse matrices in internal format
call solve_iterm(x,rs,sol)	Solves: x sol=rs iteratively by SOR	
call default_iter (conv,maxround,relax, zerosol)	Changes default iteration parameters	All parameters are optional; default values are: conv(ergence criterion)=1e-10, max round(s)=1000, relax(ation factor)=1.0, zerosol(utions ar beginning of iteration) = .true.
x=block(y,i1,i2,j1,j2)	Selects block from y: x=y(i1:i1,j1:j2)	does not work on dense_symm format; may not work with unsymmetric blocks from symmetric matrices
q=quadrf(u,x,v)	q=u'Xv	real(8) function; does not work on dense_symm format
tr=trace(x,y)	Self explanatory	real(8) function; x and y must be in same formats; works on densem and sparse_ija formats only
tr=traceblock(x,y,i1,i2,j1,j2)	tr=trace(xy(i1:i2,j1:j 2))	Works as a block-trace combination; produces correct results when blocks of y are nonsymmetric

<sup>1</sup>The hash matrix is allocated for a default number of elements. If the default is too small, the hash matrix is enlarged automatically. To change the default p elements, use call zerom(x,n,p). One matrix element in hash format takes 12 bytes, and for efficient operation there should be at least 10% more nonzero elements available than used.

All operations assume that the densem type is general while all the other types are upperstored.

Operations tr, quadf work with both upper- and full-stored matrices but the block operation works literally, i.e., selecting a lower block would return an empty matrix and selecting an upper block

would return only an upper-stored matrix. This could be a source of incompatibility between densem and other formats that use the block operation without taking its limitations into consideration. Potential problems can be noticed in examples by printing matrices of interest.

## Storage type

Matrices in the hash or ija format are half-stored by default. To change the storage type to full, add the option 'f' to the addm subroutine: call addm (a,i,j,x,'f') The subsequent conversion to the ija format will also be full-stored. For conversion from half-stored hash matrix to full-stored ija, please see a documentation for the GIBBS module.

The printing and other functions/subroutines have been designed for half-stored hash and ija matrices. Results may not be correct with full-stored matrices.

#### **Numerical accuracy**

Module KINDS defines precision r4 to be equivalent to real\*4, and r8 to be equivalent to r8. Precision rh can be set up to r4 or r8 dependent on whether memory or precision is more important.

Formats DENSEM, DENSE\_SYMM, and SPARSE\_IJA use precision r8. Format SPARSE\_HASHM uses precision rh. Whenever the precision of numbers in SPARSEM functions/subroutines is not specified, it is of type rh. Setting rh to r4 is useful when memory usage needs to be reduced, e.g., for large BLUP programs. Setting rh to r8 is necessary when numerical accuracy is important, e.g., in variance component programs, and is usually a safer choice.

## **Diagnostics**

Printing of some diagnostic messages depends on the value of an integer variable sparsem\_msg. The value of 3 means maximum diagnostic messages while the value of 0 means no diagnostic messages. The default is 2. This variable can be set in any part of the application program using the module SPARSEM.

#### FSPAK90

FSPAK is a sparse matrix package written in F77 that performs operations on sparse matrices in format SPARSE\_IJA. Operations include solving a system of linear equations by factorization, calculating a (log)determinant or finding a sparse inverse of a matrix. A sparse inverse is such a matrix that contains inverse values only for those elements that were nonzero in the original matrix. For sparse matrices, FSPAK is very efficient computationally.

FSPAK90 is a F90 interface written to simplify the use of FSPAK.

#### A complete call to FSPAK90 is:

```
call fspak90(operation,ija,rs,sol,det,msglev,maxmem,rank)
where
    operation= "factorize" - calculate sparse factorization
```

"invert" - calculate sparse inverse
"solve" - solve a system of equation

"reset" - reset the storage
"det" - calculate determinant

"stat" - print statistics

"fact\_mult" - multiplication by Cholesky factor of the reordered

matrix (if LL=IJA; sol=L\*rs)

"inv\_fact\_mult" - solve the system formed by the Cholesky factor of the reordered matrix (sol: L\*sol=rs)

ija = matrix in SPARSE\_IJA form
rs = real (r4) or (r8) vector of right hand side,
sol = real (r4) or (r8), identical to precision of rs, vector of solutions
det = real (r8) determinant or log-determinant
msglev= message level from 0 (minimum) to 3 (maximum); default=0
maxmem=maximum memory available in the system; default=infinite
rank=rank of matrix

All the arguments of fspak90 except "operation" and "ija" are optional except when they are needed in a specific "operation". Thus, rs and sol are needed for solving and det for "det" or "ldet".

## Examples:

*To solve:* 

```
call fspak90('solve',ija,rs,sol)
```

for both rs and sol either in single or double precision; all. Preceding steps are done automatically.

*To solve using double precision right hand side and solutions:* 

```
call fspak90('solve',ija,rs8=rs,sol8=sol)
```

*To sparse invert:* 

```
call fspak90('invert',ija)
```

*To obtain the determinant d:* 

To obtain the log determinant ld:

```
call fspak90('ldet',ija,det=ld)
```

*To obtain rank r with any operation:* 

To force new factorization, when the input matrix has changed: call

```
fspak90('factor',ija)
```

To deallocate the internal memory:

```
call fspak90('reset')
```

To limit memory to a maximum od maxmem, e.g., 20,000k, with any operation call

```
fspak90(...., maxmem=20000)
```

Note that only relevant arguments for each step need to be included in calling FSPAK90. Reordering is performed the first time when FSPAK90 is called. Subsequent factorization except after the option "reset" will reuse the ordering. Subsequent solves will reuse the factorization.

Additionally:

```
To sample y from N(0,A) where x \sim N(0,1) call fspak90 ('fact_mult', A, rs8=x, so18=y)

To sample y from N(0,A^{-1}) where x \sim N(0,1) call fspak90 ('inv_fact_mult', A, rs8=x, so18=y)
```

For details of the last operations, see Appendix S2

Additional subroutines and functions:

Function

```
y=mult(A,x)

y=mult(x,A)
```

Implements the matrix by vector multiplication for all matrix formats except dense\_symm, and for double precision x and y.

Subroutine

 $call\ multmatscal(A,x)$ 

Implements A=A\*x for all matrix formats except dense\_symm, and for double precision x.

## Hints on using SPARSEM

Initially all the matrices can be implemented in DENSEM format. After the program works well with an example, convert all data structures for potentially large matrices to sparse formats and verify that same results are obtained.

#### Compiling

Matrix types and functions subroutine are defined in module sparsem. Subroutine fspak90 is in module sparseop. Program xx.f90 can be compiled as

```
f90 -Maa xx.f90 aa/sparsem.a
```

where aa is the directory containing the modules and the library, and M is the option to include module directory.

Beginning in May, 1999, SPARSEM is part of a programming package that includes BLUPF90, REMLF90, GIBSF90 etc. Compilation for several Unix environments is automated by makefiles. To find details, read Readme and Installation files in the package distributions. To create application with SPARSEM and possibly other modules, create a subdirectory in the main directory of the package, and adapt a makefile from the existing directory, e.g., blup.

Sample Programs

Dense matrix solution program

```
program test_sparse_structures
use sparsem; use kinds type
(densem)::x
integer,parameter ::n=5
integer :: i,j
real (rh):: rs(n), sol(n), val
call init(x)
call zerom(x,n)
! set up a sample matrix
do i=1, n
 rs(i) = n+1-i
 val=10.0*i/i
  call addm(val,i,i,x)
  do j=i+1,n
   val=10.0*i/j
    call addm(val,i,j,x); call addm(val,j,i,x)
  enddo
enddo
print*,'rs: ',rs print*,'matrix' ; call printm(y)
call solve iterm(y,rs,sol) !solve iteratively
print*,'sol: ',sol
end
```

# Triangular dense matrix iterative-solution program

```
type (dense_symm)::x
.....
(The rest of the program remains identical)
```

#### Sparse hash matrix iterative-solution program

```
type (sparse_hashm)::x
```

#### Sparse IJA matrix iterative-solution program

Matrix in ija form cannot be set up directly but can be converted from hash form.

```
type (sparse_hashm)::x
type (sparse_ija)::y
...
y=x !conversion
```

```
call reset(x) ! Optional statement to release storage
print*,'rs: ',rs print*,'matrix' ; call printm(y) call
solve_iterm(y,rs,sol)
print*,'sol: ',sol
end
```

# Sparse IJA matrix finite-solution and inversion program with FSPACK90

```
use sparsem use sparseop !fspak90 is in module sparseop
....
call fspak90('solve',y,rs,sol)
....
!now invert call
fspak90('invert',y)
call printm(y)
end
```

real (8), pointer::a(:) !will be a(m)
end type
```

## Accessing structures

Structures can be accessed within the application program using the "%" symbol. This is useful, e.g., when using Fortran 77 programs. The example below shows how to use a determinant program written in F77.

```
type (densem):: z
integer::i,j
real (rh)::value
call init(z)
call zerom(x, 2)
! initialize z
do i=1, 2
   do j=1,2
     value=i**j/10.
     call addm(value, i,j,z)
   enddo
enddo
print*, det(z%n,z%x)
end
function det(n,x)
!calculate determinant for a 2x2 matrix
integer n
real (r8):: x(n,n), det!
det = x(1,1) *x(2,2) /x(1,2) /x(2,1)
end
```

#### Library

The following files are compiled into the library:

```
kind.f90
                - definitions of precisions
sparse.f90
                - type definitions + main subroutines,
                - supporting subroutines (in f77),
sparse2.f
fspak.f90
                - f90 interface to fspak
fspak.f
                - main fspak subroutine (in f77),
fspaksub.f
                - supporting fspak subroutines (in f77),
sparssub.f
                - low-level subroutines from the book of George and Liu (in f77),
                - timing subroutine specific to each computer (in f77).
second.f
```

Subroutines second() specific to other computers can be found in the FSPAK manual.

# **Appendix S2**

Multiplication and solving using factors

Let A be a matrix. Factorization produced by FSPAK is L:

where P is a reordering matrix chosen to minimize the size of L:

Operation "fact\_mult" multiplies the factor by a vector:

Operation "inv\_fact\_mult" solves the system of equation:

This is equivalent to:

Both operations were programmed by Juan Pablo Sanchez. The operations are useful for generation of large random samples from a multivariate normal distribution. They may be useful in Gibbs sampler algorithms when setting up and factorization of the system of equations in each round are feasible.

#### **Module Prob**

Probability routines for use in threshold models and Gibbs sampling

Written by: Ignacy Misztal and Deukhwan Lee, University of Georgia e-mail:

ignacy@uga.edu, 04/29/99-04/19/2001

Module Prob is a collection of random number generators / probabilities / truncated distributions useful for Gibbs sampling and for threshold models. The module uses features of Fortran 90 to simplify programming and high-level optimization to reduce running time, with simplicity being as important as efficiency. To understand the module fully, please read the documentation on SPARSEM and on BLUPF90.

Module prob uses high-quality generators from public domain package RANLIB for random number generators. Some low level code is from Luis Varona.

#### **Subroutines/functions**

call set\_seed(n)

Sets seed for random number generator to integer n. If this subroutine is not called, the seed will be selected by the system.

```
x=gen uniform(a,b)
```

a,b - both real (r\*) or both integers or both missing.

If a,b are missing, generates samples from uniform(0,1) distribution

If a,b are real (r8), generates samples from uniform(a,b) distribution

If a,b are integers, generates random integer between a and b

```
x=gen_normal(mean, var)
```

mean - (r8) scalar or vector

var - (r8) scalar or square matrix

x - (r8) scalar or square matrix

Generates x=N(mean,Var) when mean and var are scalars, or x=MVN(mean,Var) when mean is a vector and Var is a matrix. Arguments mean and var are optional. If they are missing, sampling is from N(0,1)

```
x=gen_invwishart(inv_q_form,df)
```

inv\_q\_form - (r8) scalar or square matrix containing inverse of quadratic form

df - an integer containing degrees of freedom

Generates samples from inverted chi square or inverted Wishart distributions.

```
y=normal(x)
```

x - real(r8) scalar

y - real (r8) contains density(X) for N(0,1)

```
y=normal_cdf(x)
x - real (r8) scalar
y - real (r8) cumulative distribution function for N(0,1)

y=normal_invcdf(x)
x - real (r8) scalar in the range of <0,1>
y - real (r8) as in: x=normal_cdf(y)

y=generate_trunc_normal(a,b,mean,var)
y - real (r8) scalar or vector
a,b - real (r8) lower and upper bound of random samples
mean - real(r8) scalar or vectors of mean, optional if scalar
var - real(r8) variance or covariance matrix, optional if scalar
```

If mean and var are missing, generates random samples from N(0,1) distribution truncated to interval <a,b>.

If mean and var are scalars, generates random samples from N(mean,var) distribution truncated to interval <a,b>.

If mean is a vector and var is a matrix, generates random samples from MVN(mean,var) distribution with first dimension truncated to interval <a,b>.

## Other functions/subroutines

New functions/subroutines are added to Module prob periodically. Please see program prob.f90 for details.
