The human genome holds an extraordinary trove of information about human development, physiology, medicine and evolution. Here we report the results of an international collaboration to produce and make freely available a draft sequence of the human genome. We also present an initial analysis of the data, describing some of the insights that can be gleaned from the sequence

The rediscovery of Mendel's laws of heredity in the opening weeks of coordinate regulation of the genes in the clusters. the 20th century1-3 sparked a scientific quest to understand the • There appear to be about 30,000-40,000 protein-coding genes in nature and content of genetic information that has propelled the human genome-only about twice as many as in worm or fly. biology for the last hundred years. The scientific progress made However, the genes are more complex, with more alternative falls naturally into four main phases, corresponding roughly to the splicing generating a larger number of protein products. four quarters of the century. The first established the cellular basis of The full set of proteins (the 'proteome') encoded by the human heredity: the chromosomes. The second defined the molecular basis genome is more complex than those of invertebrates. This is due in of heredity: the DNA double helix. The third unlocked the informational basis of heredity, with the discovery of the biological mechanism by which cells read the information contained in genes and with vertebrates appear to have arranged pre-existing components into a the invention of the recombinant DNA technologies of cloning and richer collection of domain architectures. sequencing by which scientists can do the same.

The last quarter of a century has been marked by a relentle to decipher first genes and then entire genomes, spawning 1 of genomics. The fruits of this work already include the sequences of 599 viruses and viroids, 205 naturally oc plasmids, 185 organelles, 31 eubacteria, seven archae fungus, two animals and one plant.

Here we report the results of a collaboration involving 20 from the United States, the United Kingdom, Japan, Germany and China to produce a draft sequence of the genome. The draft genome sequence was generated from a J map covering more than 96% of the euchromatic part of the genome and, together with additional sequence in public da it covers about 94% of the human genome. The sequer produced over a relatively short period, with coverage risit about 10% to more than 90% over roughly fifteen mont sequence data have been made available without restricti updated daily throughout the project. The task ahead is to pr finished sequence, by closing all gaps and resolving all amb Already about one billion bases are in final form and the bringing the vast majority of the sequence to this standard straightforward and should proceed rapidly.

The sequence of the human genome is of interest in respects. It is the largest genome to be extensively sequence being 25 times as large as any previously sequenced geno eight times as large as the sum of all such genomes. It is t vertebrate genome to be extensively sequenced. And, uniqu the genome of our own species.

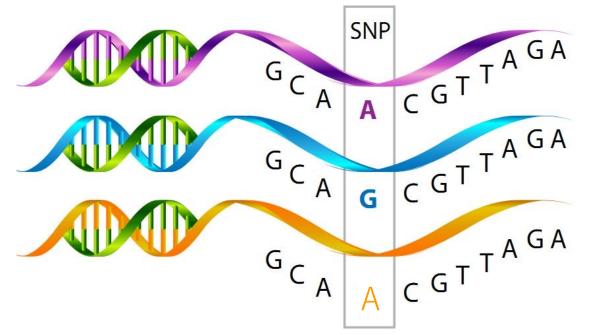

Much work remains to be done to produce a complete t sequence, but the vast trove of information that has available through this collaborative effort allows a global peron the human genome. Although the details will change sequence is finished, many points are already clear.

• The genomic landscape shows marked variation in the d tion of a number of features, including genes, trans elements, GC content, CpG islands and recombination ra gives us important clues about function. For example, the opmentally important HOX gene clusters are the most repe regions of the human genome, probably reflecting the very c

Genetic polymorphism in varietal identification and genetic improvement*

M. Soller¹ and J. S. Beckmann²

¹ Department of Genetics, The Hebrew University of Jerusalem, 91904 Jerusalem, Israel

² Institute of Field and Garden Crops, Agricultural Research Organization, The Volcani Center 50250 Bet Dagan, Israel

Received July 14, 1982; Accepted July 3, 1983 Communicated by A. Robertson

Summary. New sources of genetic polymorphisms promise significant additions to the number of useful genetic markers in agricultural plants and animals, and prompt this review of potential applications of polymorphic genetic markers in plant and animal breeding. Two major areas of application can be distinguished. The first is based on the utilization of genetic markers to determine genetic relationships. These applications include varietal identification, protection of breeder's rights, and parentage determination. The second area of application is based on the use of genetic markers to identify and map loci affecting quantitative traits, and to monitor these loci during introgression or selection programs. A variety of breeding applications based on Use of DNA polymorphisms as genetic markers

- Construct genetic relationships
- Parentage determination
- Identification of QTL

- Genotyping will become cheap
 - Thousands of SNP
- Compute GEBV based on SNP
 - High accuracy
 - Animals with no phenotypes
 - Select the best animals earlier

Genotyping became cheaper in 2008

- First genomic evaluation for dairy and beef cattle in 2009
 - \$300 in 2009 vs. \$30 in 2022
 - 50,000 SNP

What about statistical methods able to fit genomic information?

Statistical methods before genomics

- BLUP (Henderson, 1949 1976)
 - Best: minimizes MSE
 - Linear: linear function of the data
 - Unbiased: $E(u) = E(\hat{u})$
 - Prediction: for random effects

Statistical Science 1991, Vol. 6, No. 1, 15–51

That BLUP Is a Good Thing: The Estimation of Random Effects

G. K. Robinson

$$\begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{W} \\ \mathbf{W}'\mathbf{X} & \mathbf{W}'\mathbf{W} + \mathbf{A}^{-1}\frac{\sigma_e^2}{\sigma_u^2} \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{\beta}} \\ \widehat{\mathbf{u}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\mathbf{y} \\ \mathbf{W}'\mathbf{y} \end{bmatrix}$$

Henderson's MME

• Model

 $\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{W}\mathbf{u} + \mathbf{e}$

• Joint probability of phenotypes and EBV

$$p(\mathbf{y},\mathbf{u}) = p(\mathbf{u}|\mathbf{y}) p(\mathbf{y}) = p(\mathbf{y}|\mathbf{u}) p(\mathbf{u})$$

• Joint probability density function of phenotypes and EBV

$$p(\mathbf{y},\mathbf{u}) = p(\mathbf{y}|\mathbf{u}) \ p(\mathbf{u}) = \frac{1}{\sqrt{2\pi|\mathbf{R}|}} e^{-\frac{1}{2}(\mathbf{y}-\mathbf{X}\boldsymbol{\beta}-\mathbf{W}\mathbf{u})'\mathbf{R}^{-1}(\mathbf{y}-\mathbf{X}\boldsymbol{\beta}-\mathbf{W}\mathbf{u})} \ \frac{1}{\sqrt{2\pi|\mathbf{R}|}} e^{-\frac{1}{2}(\mathbf{u}-\mathbf{0})'\mathbf{G}^{-1}(\mathbf{u}-\mathbf{0})}$$

$$\begin{cases} \mathbf{X}'\mathbf{R}^{-1}\mathbf{X}\boldsymbol{\beta} + \mathbf{X}'\mathbf{R}^{-1}\mathbf{W}\mathbf{u} = \mathbf{X}'\mathbf{R}^{-1}\mathbf{y} \\ \mathbf{W}'\mathbf{R}^{-1}\mathbf{X}\boldsymbol{\beta} + (\mathbf{W}'\mathbf{R}^{-1}\mathbf{W} + \mathbf{G}^{-1})\mathbf{u} = \mathbf{W}'\mathbf{R}^{-1}\mathbf{y} \end{cases} \begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{W} \\ \mathbf{W}'\mathbf{X} & \mathbf{W}'\mathbf{W} + \mathbf{A}^{-1}\frac{\sigma_e^2}{\sigma_u^2} \\ \sigma_u^2 \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{\beta}} \\ \widehat{\mathbf{u}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\mathbf{y} \\ \mathbf{W}'\mathbf{y} \end{bmatrix}$$

From 1989 to 2009

• How to add genomic information to the evaluation system in 2009?

Multistep

Bayesian Alphabet

- SNP effect models = outputs SNP effects
- BayesA (Meuwissen et al., 2001)
 - All SNPs have effect on the trait (few with large effect) $a_i \sim N(\mu, \sigma_{a_i}^2)$
 - Different variances for each SNP

• BayesB (Meuwissen et al., 2001)

•
$$p(a_i | \sigma_{a_i}^2, \pi) = \begin{cases} t(0, v, \sigma_{a_i}^2) \text{ or } N(0, \sigma_{a_i}^2) \text{ with probability } (1 - \pi) \\ 0 \text{ with probability } \pi \end{cases}$$

• When π = 0, BayesB becomes BayesA

Bayesian Alphabet

• BayesC (Habier et al., 2011)

•
$$p(a_i | \sigma_a^2) = \begin{cases} N(0, \sigma_a^2) \text{ with probability } (1 - \pi) \\ 0 \text{ with probability } \pi \end{cases}$$

- BayesR (Erbe et al., 2012)
 - $p(a_i|\pi, \sigma_a^2) = \pi_1 \times N(0, 0 \times \sigma_a^2) + \pi_2 \times N(0, 10^{-4} \times \sigma_a^2) + \pi_3 \times N(0, 10^{-3} \times \sigma_a^2) + \pi_4 \times N(0, 10^{-2} \times \sigma_a^2)$
- BayesRC (MacLeod et al., 2016)
 - BayesR using biological information to assign SNP to classes
- High computing cost and simple models
- After > 10 years, assumption of normality is good enough!

SNP-BLUP (ridge regression)

- SNP effect model = outputs SNP effects
- $a \sim N(0, \sigma_a^2)$

$$y = X\beta + Za + e$$

$$\begin{bmatrix} X'X & X'Z \\ Z'X & Z'Z + I \frac{\sigma_e^2}{\sigma_a^2} \end{bmatrix} \begin{bmatrix} \widehat{\beta} \\ \widehat{a} \end{bmatrix} = \begin{bmatrix} X'y \\ Z'y \end{bmatrix}$$

• All SNP explain the same proportion of variance on the trait

 $GEBV = Z\hat{a}$

SNP-BLUP (ridge regression)

- SNP effect model = outputs SNP effects
- All SNP explain the same proportion of variance on the trait

Understanding SNP variance

$$\sigma_a^2 = \frac{\sigma_u^2}{2\sum_{i=1}^{SNP} p_i (1-p_i)}$$

How do we get the variance of SNP effects, σ_a^2 ?

1) You can estimate it (Bayes C, REML)

2) You can « guess » from the <u>genetic variance</u> σ_u^2 SNP 1 contributes $2p_1q_1a_1^2$ to the genetic variance SNP 2 contributes $2p_2q_2a_2^2$ to the genetic variance

$$\sigma_u^2 = 2\sum p_i q_i a_i^2 \approx 2\left(\sum p_i q_i\right) \times \overline{(a_i^2)} \approx 2\left(\sum p_i q_i\right) \sigma_a^2$$

Reversing the expression gives

$$\sigma_a^2 \approx \frac{\sigma_u^2}{2(\sum p_i q_i)}$$

GBLUP: equivalent to SNP-BLUP

- GEBV-based model = outputs genomic predictions
- $u \sim N(0, \sigma_u^2)$

 $\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{W}\mathbf{u} + \boldsymbol{e}$

$$\begin{bmatrix} \mathbf{X'X} & \mathbf{X'W} \\ \mathbf{W'X} & \mathbf{W'W} + \mathbf{G}^{-1} \frac{\sigma_e^2}{\sigma_u^2} \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{\beta}} \\ \widehat{\mathbf{u}} \end{bmatrix} = \begin{bmatrix} \mathbf{X'y} \\ \mathbf{W'y} \end{bmatrix}$$

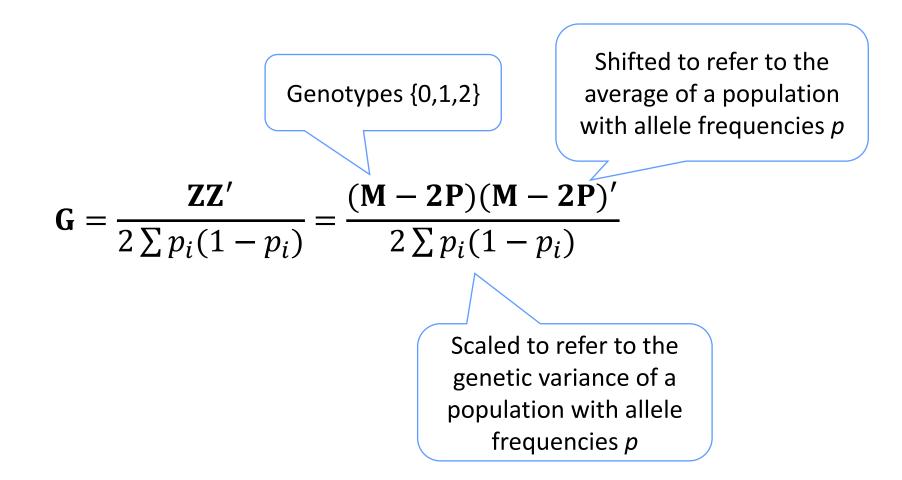

Bernardo (1994) Nejati-Javaremi et al. (1997)

$$\mathbf{G} = \frac{\mathbf{Z}\mathbf{Z}'}{2\sum p_i(1-p_i)}$$

VanRaden (2008)

Genomic relationship matrix

What are genomic relationships?

- Relationships were conceived as standardized covariances (Fisher, Wright)
 - $Cov(u_i, u_j) = R_{ij}\sigma_u^2$
 - R_{ij} "some" relationship
 - σ_u^2 genetic variance
- True relationships: two individuals are genetically identical (for a trait) if they carry the same genotype at the causal QTL or genes
- Genomic relationships: due to shared (Identical By State) alleles at *causal genes*
 - If I share the blood group A with someone, we are like twins!
 - Most of the genes are unknown
 - We use proxies (SNP markers)

Early use of markers to infer A

• A = pedigree relationships: due to shared (Identical By Descent) alleles at *causal genes*

- In conservation genetics
- Gather markers, then reconstruct pedigrees, then construct **A**
 - Either estimates of A_{xy}, or estimates of « the most likely relation » (son-daughter, cousins, whatever) Li and Horvitz 1953, Cockerham 1969, Ritland 1996, Caballero & Toro 2002, and many others
- With abundant marker data we can do better than this

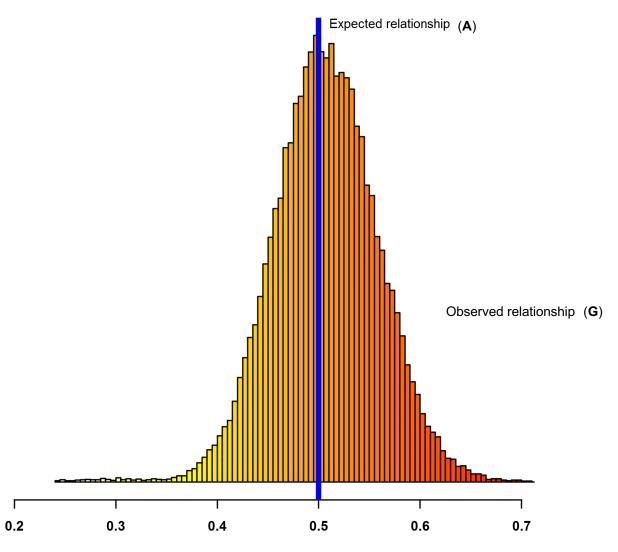

Pedigree vs. Genomic relationships

- Identical By Descent Relationships based on pedigree are average relationships which assume infinite loci
- « Real » IBD relationships are a bit different due to finite genome size (Hill and Weir, 2010)
- Therefore **A** is the <u>expectation</u> of realized or observed relationships
- SNPs more informative than **A**
 - Two full sibs might have a correlation of 0.4 or 0.6
- Many markers needed to better estimate relationships
 - Estimators of IBD

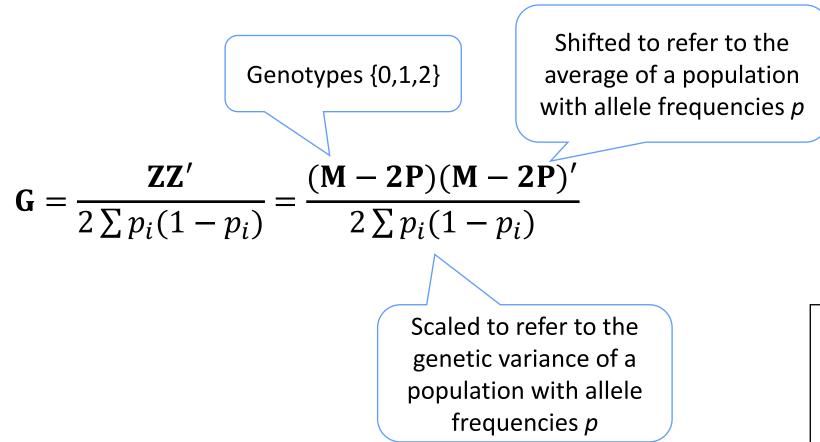

Pedigree vs. Genomic relationships

Genomic relationship for full-sibs

Genomic relationships

If base allelic frequencies are used, **G** is an unbiased an efficient estimator of IBD realized relationships

Some "interesting" properties of G

- If *p* are computed from the data This implies that E(Breeding Values)=0
- Positive and negative inbreeding Some individuals are more heterozygous than the average of the population (OK, no biological problem)
- Positive and negative genomic relationships
 Individuals *i* and *j* are more distinct than an average pair of individuals in the data
 Fixing negative estimates of relationships to 0 is a wrong praxis

Some "interesting" properties of G

- VanRaden (2008)
 - **G** can be singular if few SNP or identical genotypes (twins)
 - **G** must be singular if number of individuals > number of SNP
- Stranden and Christensen (2011)
 - **G** is singular if *p*'s are averages across the sample

$$G = 0.95 \frac{ZZ'}{2\sum p_i(1-p_i)} + 0.05I$$
 OR $G = 0.95 \frac{ZZ'}{2\sum p_i(1-p_i)} + 0.05A$ \rightarrow $G = \alpha G_0 + \beta A$

• Blending \approx Adding a residual polygenic effect

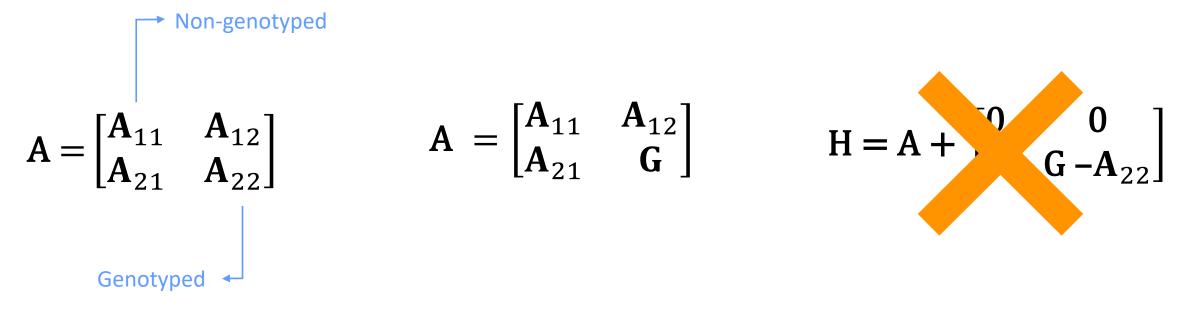

Some "interesting" properties of G

- For all matrices of the kind $\mathbf{G} = \frac{\mathbf{Z}\mathbf{Z}'}{2\sum p_i(1-p_i)} = \frac{(\mathbf{M}-\mathbf{2}\mathbf{P})(\mathbf{M}-\mathbf{2}\mathbf{P})'}{2\sum p_i(1-p_i)}$
 - We don't need to put the same p's in the upper and and in the lower part
- Changing allele frequencies in **P** shifts EBV's by a constant
 - Irrelevant if there is an overall mean or fixed effect in the model (Stranden and Christensen, 2011)
- Changing allele frequencies in $\frac{1}{2\sum p_i q_i}$ "scales"

Not all individuals are genotyped

- Genomic evaluation would be simpler if all animals were genotyped
- What to do when there are genotyped and non-genotyped individuals?
 - SNPs are capturing relationships
 - Pedigrees give information about relationships
 - Genomic and pedigree relationships can be combined in a single matrix!

Not all animals are genotyped

- Genomic info can be extended to non-genotyped animals
 - joint distribution of EBV for non-genotyped (u₁) and genotyped (u₂)

 $p(u_1, u_2) = p(u_2)p(u_1|u_2)$ Legarra et al., 2009

$$\mathbf{H} = \begin{pmatrix} var(u_1) & cov(u_1, u_2) \\ cov(u_2, u_1) & var(u_2) \end{pmatrix} = \begin{pmatrix} \mathbf{A}_{11} + \mathbf{A}_{12}\mathbf{A}_{22}^{-1}(\mathbf{G} - \mathbf{A}_{22})\mathbf{A}_{22}^{-1}\mathbf{A}_{21} & \mathbf{A}_{12}\mathbf{A}_{22}^{-1}\mathbf{G} \\ \mathbf{G}\mathbf{A}_{22}^{-1}\mathbf{A}_{21} & \mathbf{G} \end{pmatrix}$$

$$Variance of prediction of genotypes for non-genotyped animals Prediction generates a covariance descent a c$$

Understanding H

- It is a projection of **G** matrix on the rest of individuals "so that" **G** matrix makes sense
 - e.g. parents of two animals related in **G** should be related in **A**
- It is a Bayesian update of the pedigree matrix based on new information from genotypes

- Typically
 - A in the millions
 - **G** and **A**₂₂ in the thousands
 - Leads to a very efficient method of genomic evaluation:

Some properties of H

- <u>Always</u> semi-positive definite
 - eigenvalues are always positive or zero
- Positive definite & invertible if **G** is invertible
- In practice, if **G** is too different from A_{22} (wrong pedigree or genotyping), this gives lots of numerical problems
- If no one is genotyped, Single-step is BLUP
- If everyone is genotyped, Single-step is GBLUP

Realized relationship matrix (H)

Animal	Sire	Dam
1	0	0
2	0	0
3	1	2
4	1	2

Pedigree Relationship Matrix (A)	Genomic Relationship Matrix (G) for animals 3 and 4	Realized Relationship Matrix (H)			
$\begin{bmatrix} 1.0 & 0.0 & 0.5 & 0.5 \\ . & 1.0 & 0.5 & 0.5 \\ . & . & 1.0 & 0.5 \end{bmatrix}$		[1.004	0.0 1.004	0.507 0.507 <u>1.0</u>	0.507 0.507 0.52

Single-step Genomic BLUP (ssGBLUP)

- Because not all animals are genotyped
 - 5 to 10% in large populations

$$\begin{bmatrix} \mathbf{X'X} & \mathbf{X'Z} \\ \mathbf{Z'X} & \mathbf{Z'Z+H^{-1}} \frac{\sigma_e^2}{\sigma_u^2} \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{\beta}} \\ \widehat{\mathbf{u}} \end{bmatrix} = \begin{bmatrix} \mathbf{X'y} \\ \mathbf{Z'y} \end{bmatrix}$$

$$\mathbf{H}^{-1} = \mathbf{A}^{-1} + \begin{bmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{G}^{-1} - \mathbf{A}_{22}^{-1} \end{bmatrix}$$

Aguilar et al., 2010 Christensen and Lund, 2010

Combining two sources of relationships

$$\mathbf{H} = \mathbf{A} + \begin{bmatrix} \mathbf{A}_{12}\mathbf{A}_{22}^{-1}(\mathbf{G} - \mathbf{A}_{22}) \mathbf{A}_{22}^{-1}\mathbf{A}_{21} & \mathbf{A}_{12}\mathbf{A}_{22}^{-1}(\mathbf{G} - \mathbf{A}_{22}) \\ (\mathbf{G} - \mathbf{A}_{22}) \mathbf{A}_{22}^{-1}\mathbf{A}_{21} & \mathbf{G} - \mathbf{A}_{22} \end{bmatrix}$$

• A

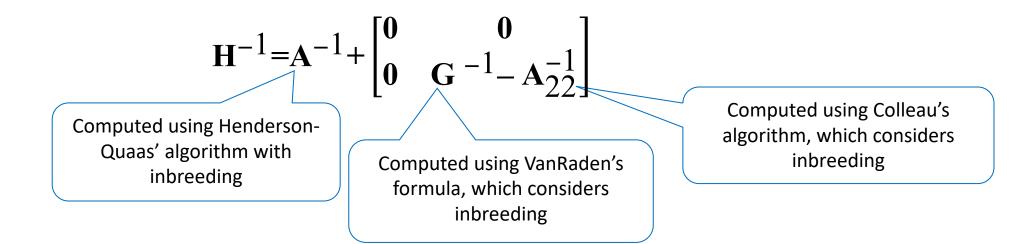

- Contains expected relationships
- Is limited by the pedigree depth and completeness
- Depends on accuracy of recording pedigrees

• G

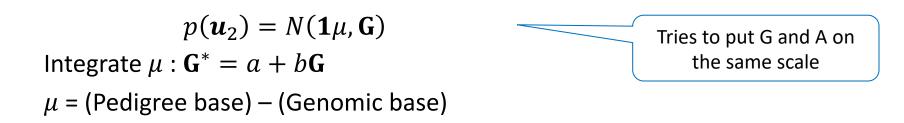

- Contains number of alleles shared between animals weighted by heterozygosity
- No limitations regarding to the number of past generations
- Depends on allele frequency and quality of genomic data

Combining two sources of relationships

- Tuning
 - Base of **G** is *genotyped* animals
 - Base of **A** is founders of the pedigree
 - For SSGBLUP, Vitezica et al. 2011 modeled a mean in genotyped animals:

Single-step

$$\begin{bmatrix} \mathbf{X'X} & \mathbf{X'Z} \\ \mathbf{Z'X} & \mathbf{Z'Z} + \mathbf{H}^{-1} \frac{\sigma_e^2}{\sigma_u^2} \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{\beta}} \\ \widehat{\mathbf{u}} \end{bmatrix} = \begin{bmatrix} \mathbf{X'y} \\ \mathbf{Z'y} \end{bmatrix}$$

Misztal et al. (2009) Legarra et al. (2009) Aguilar et al. (2010) Christensen & Lund (2010)

$$\begin{bmatrix} \mathbf{X}'\mathbf{X} & \mathbf{X}'\mathbf{Z}\mathbf{M} & \mathbf{X}'_{n}\mathbf{Z}_{n} \\ \mathbf{M}'\mathbf{Z}'\mathbf{X} & \mathbf{M}'\mathbf{Z}'\mathbf{Z}\mathbf{M} + \mathbf{I}\frac{\sigma_{\mathbf{e}}^{2}}{\sigma_{\alpha}^{2}} & \mathbf{M}'_{n}\mathbf{Z}'_{n}\mathbf{Z}_{n} \\ \mathbf{Z}'_{n}\mathbf{X}_{n} & \mathbf{Z}'_{n}\mathbf{Z}_{n}\mathbf{M}_{n} & \mathbf{Z}'_{n}\mathbf{Z}_{n} + \mathbf{A}^{nn}\frac{\sigma_{\mathbf{e}}^{2}}{\sigma_{g}^{2}} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\alpha}} \\ \hat{\boldsymbol{\epsilon}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\mathbf{y} \\ \mathbf{M}'\mathbf{Z}'\mathbf{y} \\ \mathbf{Z}'_{n}\mathbf{y}_{n} \end{bmatrix}$$

ssSNPBLUP or ssBR
